Version 1.3.2 April 2015

Credits

We thank the developers of the Meta Programming System, who have developed MPS since the early 2000. MetaR would not have been possible without them.

MPS Project leaders, in chronological order: Sergey Dmitriev, Igor Alshannikov, Konstantin Solomatov and Alexander Shatalin. **Current team members:** Alexander Shatalin, Fedor Isakov, Mihail Muhin, Michael Vlassiev, Václav Pech, Simon Alperovich, Daniil Elovkov, Victor Matchenko, Artem Tikhomirov, Mihail Buryakov and Alexey Pyshkin. **Earlier members of the MPS team:** Evgeny Gryaznov, Timur Abishev, Julia Beliaeva, Cyril Konopko, Ilya Lintsbah, Gleb Leonov, Evgeny Kurbatsky, Sergey Sinchuk, Timur Zambalayev, Maxim Mazin, Vadim Gurov, Evgeny Geraschenko, Darja Chembrovskaya, Vyacheslav Lukianov and Alexander Anisimov. **And these external contributors:** Sascha Lisson, Thiago Tonelli Bartolomei and Alexander Eliseyev.

We also thank the many people who have taken the MetaR training sessions at the Clinical Translational Science Center (Weill Cornell Medical College, Memorial Sloan Kettering, and Hospital for Special Surgery and Hunter College). Their feedback we received during these sessions have been instrumental in rapidly making MetaR user-friendly.

1 — Introduction

1.1 Background

The MetaR software <http://MetaR.campagnelab.org> is an example of a new kind of interactive tool for data analysis. It was developed by the Campagne laboratory using the Meta Programming System (MPS) (see <http://www.jetbrains.com/mps> [**Dmitriev:2004**]). MPS is a mature Language Workbench that makes it relatively easy to create new languages and tools to help users of these languages [**campagne2014mps**].

1.2 Intended audience

This booklet is designed to teach how to use MetaR for data analysis. In the first chapters, we will assume that you have no prior scripting or programming experience, but will expect you to know how to use a computer.

1.3 Key Concepts

High-level data abstractions

MetaR is designed to make it easier to conduct data analysis. To achieve this goal, and in contrast to programming languages such as the R language, Julia or Python, that are often low-level and require good programming skills, MetaR offers high-level data abstractions and provides assistance in manipulating data. High-level abstractions used in MetaR analyses include the following concepts:

1. Tables, Columns, Column Groups and Group usages,
2. Analyses
3. Plot
4. Model

These high-level abstractions will be explained in the following chapters.

R program generation

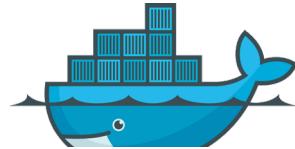

Analyses developed with MetaR are transformed into R programs when the user needs to execute them. MetaR is tightly integrated with MPS to make it seamless to run analyses without prior knowledge of the R language.

Note that while most users can use MetaR without knowledge of the R language, all users will need to install the R language in order to execute MetaR analyses.

Docker integration

Starting with version 1.3.1, MetaR can run the R scripts that it generates into Docker containers. Docker is a technology that makes it easier to obtain reproducible script executions. When MetaR does not use Docker, it is possible for the R runtime to try to install a package the first time you run an analysis with a statement that requires the package. While this should not be a problem, we found that R package installation is brittle and can sometimes fail at various time points, for a variety of reasons¹. To avoid such problems, which tend to occur when we give a training sessions, we now support running Analyses with Docker. Chapter 4 explains how to configure MetaR to use Docker for reproducible analyses.

Composable language

MetaR is built as an MPS language. In contrast to languages built with compiler technology, MPS languages are composable. Briefly, language composition is the ability to compose, or combine, two or more languages. This ability is particularly useful to extend MetaR. It is possible to define micro-languages, made of one or two statement types, that when composed with MetaR make it possible to customize MetaR for specific application domains. The EdgeR language provides an example of composition, where an R/Bioconductor package called EdgeR has been integrated with MetaR and exposes a new kind of statement to perform calls of differential expression. See Chapters 5 and 8 to learn more about language composition in MetaR.

1.4 Solutions and Models

Developing an analysis with MetaR is done by creating nodes of the MetaR concepts in MPS models. Models exist in MPS solutions. To learn how to create an MPS solution, read the preview of the MPS language workbench available at [http://campagnelab.org/publications/our-books/\[campagne2014mps\]](http://campagnelab.org/publications/our-books/[campagne2014mps]), or watch the beginning of the MetaR training video at <http://campagnelab.org/software/metar/video-tutorials/>. Figures 1.1-1.2 provide a brief walk-through of the steps you should follow to create a

¹For instance, because a new version of a package has become available which breaks compilation of the package on your machine.

Figure 1.1: The Quick Start menu. This menu is displayed when you first open MPS, or when you have no project currently open in MPS. The first item in the menu is used to create a new project.

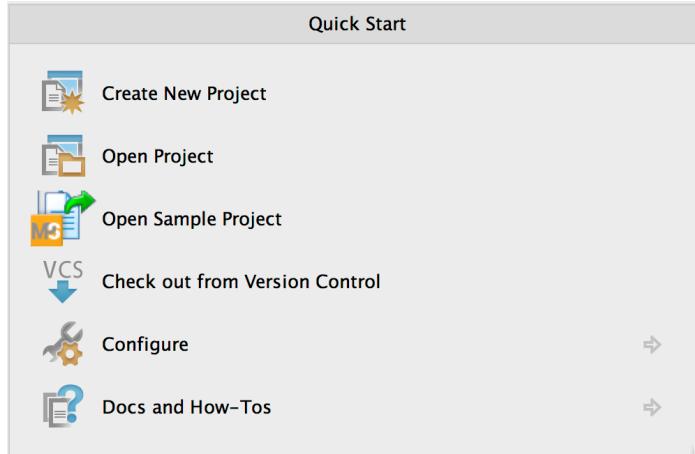

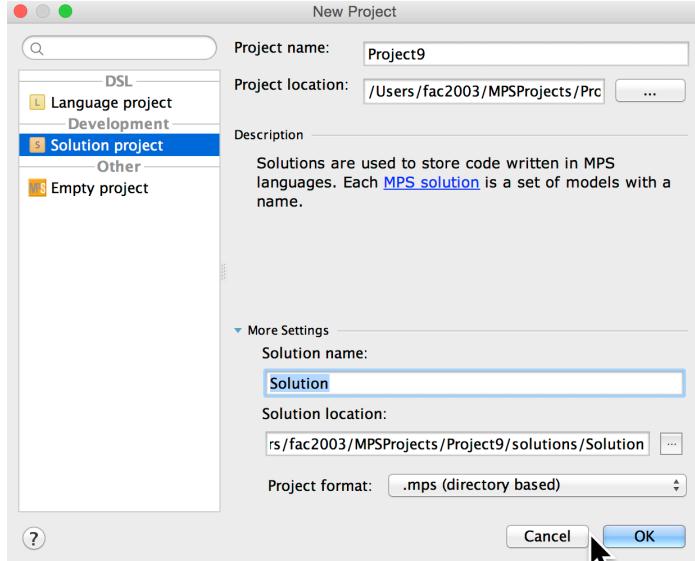

Figure 1.2: The New Project Dialog. Use this dialog to create a new Solution. Solutions are used to store models and express your solutions to specific analysis problems. Select the “Solution Project” project type on the left panel, name the project, and name the solution you wish to create.

project and solution. After the project open, open the project tab(see [campagne2014mps]) and right-click on the solution name. Import the metaR devkit and create a model.

You can create as many models as you need to store your analyses. In the following chapter, we assume that you have created a solution and at least one model in this solution.

Table Viewer Tool

2 — Tables

2.1 Overview

Before you start an analysis, you will need to define Table nodes that represent the data files needed in the analysis. MetaR explicitly models files that contain tables of data. This is done so that you can easily refer to these tables, without having to remember where the original file is located on your computer.

In this Chapter, you will learn how to

1. define a MetaR table,
2. adjust the types of the columns of the data described in the file,
3. annotate a table with groups,
4. link groups in column group usage.

2.2 Create a Table

To create a Table, right-click on a model in the project tab and select `right-click > New > o.c.metar.tables > Table`. This will create an empty table, as shown in Figure 2.1. Tables have a `name`, a `pathToResolve` attribute and a list of columns. The following paragraphs describe these attributes.

name

The table name is set automatically from the path when you use the file selection button. You can change the name to match your analysis needs and make it easier to remember what is in the table.

File Path (`pathToResolve`)

This attribute contains a path to the TSV file that you wish to analyze. The path may contain references to path variables that will be automatically resolved before MetaR attempts to load table information from the path. Path variable references can be written as `$a.b.c/data/file.tsv`. Such a reference will require you to define the `a.b.c` path variable name and associate it with a value on each machine where the table will be used.

```
Table <no name> ...
File Path
<no pathToResolve>
Columns
<no name>:
```

Figure 2.1: **New Table.** This figure presents a freshly created Table AST Root node. You can use the button located to the right, after the `<no name>` red label (`...`), to open a file selection dialog. Use this dialog to locate a TSV file to configure this table.

You can define path variables with the Preferences/Settings MPS menu (`MPS > Preferences > PathVariables` on Mac, `MPS > Settings > PathVariables` on PC).

Columns

Columns is an attribute that presents the list of columns identified in the TSV file. Each column has a name, a type, and may be annotated with a set of column groups (see Section 2.4 for details about column groups). MetaR supports the following column types, which map to the R data types:

1. **Numeric.** Any number. Technically, can be a floating number or an integer.
2. **String.** A string of characters.
3. **Boolean.** A type that can only have two values: `true` or `false`.
4. **Category.** A type that can take only a limited number of values (e.g., `{RED, GREEN, BLUE}` would be a category with these values, `(RED, GREEN and BLUE` in our example).

These types are automatically determined from the data in the table file. However, in case the automatic algorithm failed for a table, you can change the types manually. To do this, put the cursor over the name of the type in the column section, and use auto-completion in the inspector to change to the desired type.

Figure 2.2 presents a MetaR table annotated with groups.

2.3 Column Groups Container

Column Groups Containers are used to define column groups and annotate these groups with group usages. To create a new Column Group Container, right-click on a model and select `New > o.c.tables.ColumnGroupContainer`. This will create the empty container shown in Figure 2.3. You need and should have only one container per model. The container will hold the groups and group usages that you need across the MetaR Tables defined in the model.

2.4 Column Groups

Column Groups can be defined by pressing `↶` either on top of the « ... » (immediately below `Define Groups :`), when the list of groups is empty, or with the cursor immediately before the name of an existing group. Each group has a name and an optional set of group usages. Figure 2.4 presents a new column group (group for short).

```
Table GSE59364_DC_all.csv ...
File Path
  ${org.campagnelab.metaR.home}/data/GSE59364_DC_all.csv
Columns
  gene: string [ ID ]
  mRNA len: numeric [ << ... >> ]
  genomic span: numeric [ << ... >> ]
  DC_normal: numeric [ << ... >> ]
  DC_treated: numeric [ << ... >> ]
  DC0904: numeric [ LPS=NO, counts ]
  DC0907: numeric [ LPS=NO, counts ]
  DCLPS0910: numeric [ LPS=NO, counts ]
  DCLPS0913: numeric [ LPS=NO, counts ]
  A_DC: numeric [ LPS=NO, counts ]
  A_DC_LPS: numeric [ LPS=YES, counts ]
  B_DC: numeric [ LPS=NO, counts ]
  B_DC_LPS: numeric [ LPS=YES, counts ]
  C_DC: numeric [ LPS=NO, counts ]
  C_DC_LPS: numeric [ LPS=YES, counts ]
  C2DC: numeric [ LPS=NO, counts ]
  C2DCLPS: numeric [ LPS=YES, counts ]
  C3DC: numeric [ LPS=NO, counts ]
  C3DCLPS: numeric [ LPS=YES, counts ]
```

Figure 2.2: **Example Table.** The figure presents an example table annotated with groups.

Figure 2.3: **Empty Column Group Container.** Use a column group container to define column groups and associated group usages. Place the cursor over the « ... » symbol and press to add a new group or group usage. Name the group or usage immediately after creating it.

Column Groups and Usages

Define Usages:

<< ... >>

Define Groups:

<< ... >>

Figure 2.4: **New Group.** You used for << ... >> should name a new group immediately after creating it.

Column Groups and Usages

Define Usages:

```
LPS_Treatment
ID
heatmap
```

Define Groups:

```
LPS=YES used for LPS_Treatment heatmap
LPS=NO used for LPS_Treatment heatmap
ID used for ID
counts used for heatmap
```

name

The name of the group is a string that should mean something in the context of your analysis. Some MetaR analysis statements require specific group names to be defined in a model container and referenced in an input table. Other groups will be created by you with meaningful names to help identify columns that have certain properties, so that you can refer to them collectively by the group name.

used for

Column groups can be annotated with a set of group usages. You can enter references to usages already defined in the column group container following the `used for` keyword shown in Figure 2.4. Press `⌘+Space` on the « ... » to insert the first group usage. Make sure the usage is defined (its name should be visible in the `Define Usages:` section of the container (see Section 2.5 to learn how to create a new Group Usage). You can bind a group usage reference to a Group usage by using auto-completion (`ctrl+Space` to locate the name, then pressing `Enter` to accept one completion choice), or by typing the name of the group usage directly (note that group usage names are case sensitive).

 Pressing `Enter` before `<no name>` will not have the desired effect if you have not yet named a group. Make sure you name groups immediately after you create them.

2.5 Column Group Usage

A Column Group Usage can be defined by pressing `Enter` either on top of the « ... » (immediately below `Define Usages:`), when the list of group usages is empty, or with the cursor immediately before the name of an existing group usage. When the list already contains one or more group usages, you can add more by placing the cursor over a group usage name and pressing `Enter`. Keep pressing `Enter` to add more empty group usages.

Figure 2.5: Example Group Container. This example presents a container with several groups and group usages.

Figure 2.6: Content of a *Sample Annotation Table*

The SampleID column provides the name of the column to which the groups should be assigned. The Groups column provides the names of the groups, separated by a comma, which will be assigned to the column identified by SampleID.

SampleID	Groups
gene	ID
DC0904	LPS=NO,counts
DC0907	LPS=NO,counts
DCLPS0910	LPS=NO,counts
DCLPS0913	LPS=NO,counts
A_DC	LPS=NO,counts
A_DC_LPS	LPS=YES,counts
B_DC	LPS=NO,counts
B_DC_LPS	LPS=YES,counts
C_DC	LPS=NO,counts
C_DC_LPS	LPS=YES,counts
C2DC	LPS=NO,counts
C2DCLPS	LPS=YES,counts
C3DC	LPS=NO,counts
C3DCLPS	LPS=YES,counts

2.6 Example Column Group Container

Figure 2.5 presents an example of a configured Column Group Container. This container defines two groups LPS=yes and LPS=no, which can be used to annotate Table columns that contain data about gene expression of samples treated with LPS or not. The group usage LPS_Treatment is associated to both groups to indicate that they belong together and are two kinds of treatment.

2.7 Column Groups from a Table

An alternative way to automatically create Column Groups and attach them to Columns at the same time is to use a so-called annotation table. These tables are normal Table nodes (created as specified 2.2) with a special structure and content. When created, MetaR is able to recognize them and allows the user to use these tables to annotate other tables.

The structure of an annotation table requires the following two columns:

- *SampleID*: values of this column are sample names
- *Groups*: values of this column are comma-separated lists of group names

When annotation tables are available in the current model, the user can

1. open the Table to annotate
2. use the "Use Column Groups From Table: <table name>" intention (💡) when the cursor is on top of the Table node

This way, Sample IDs are matched with the column names and the groups listed in the same row are attached to the corresponding Column. In addition, if the groups are not defined in the ColumnGroupContainer, they are created in the annotation process. The ColumnGroupContainer is also created if it does not exist.

To see how this intention works in practice, we will create the same groups shown in Figure 2.2 using an annotation table. To do that, we firstly need to create a TSV file with the content shown in Figure 2.6. The next step is to load this table in a Table node (Figure 2.7). Finally, we invoke the “Use Column Groups From Table: AnnotationTableFor GSE59364_DC_all.csv” intention as shown in Figure 2.8 to apply the group names from the table to the destination Table. These steps will result in exactly the same annotated table shown in Figure 2.2.

```
Table AnnotationTableForGSE59364_DC_all.csv ...
File Path
  ${org.campagnelab.metaR.home}/data/AnnotationTableForGSE59364_DC_all.csv
Columns
  SampleID: string
  Groups: string
```

Figure 2.7: **Table with Samples and Groups.** An annotation table loaded as Table node.

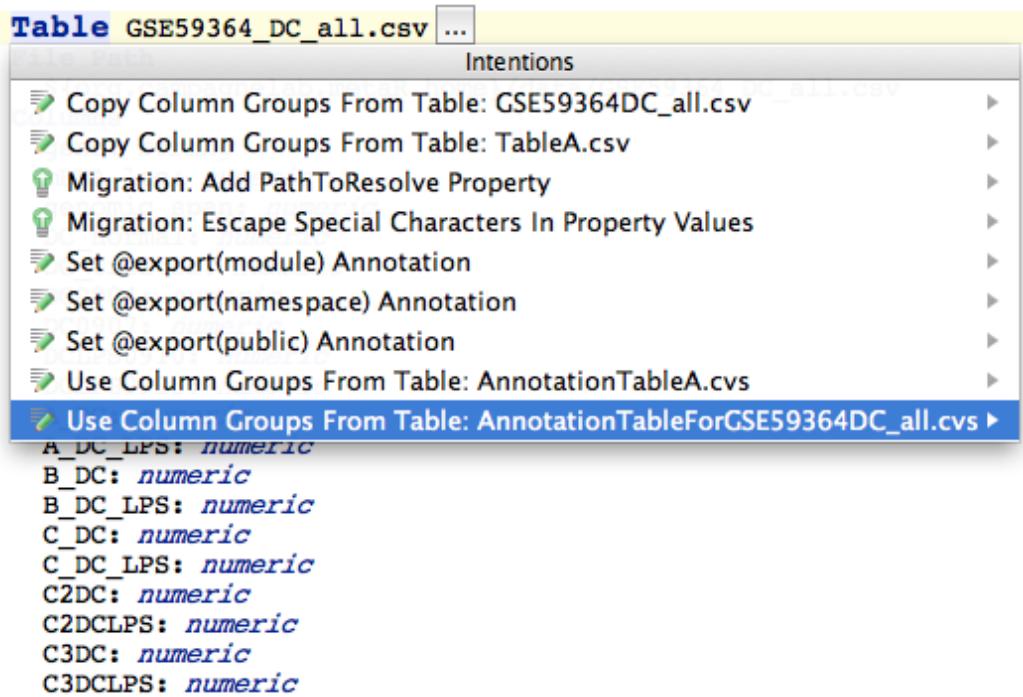

Figure 2.8: **Intention to Annotate a Table using another Table**

2.8 Column Group Annotations

Sometimes, a covariate is a continuous variable that can take different values across samples. This kind of covariate can also be used to estimate linear models (see Chapter 5 and 6).

MetaR 1.3 supports continuous covariates. Instead of creating a Column Group for each possible value of the covariate, you can indicate that values of the column group are determined using a special type of table called *Covariate Table*. A covariate table is a normal Table node in metaR with the following characteristics:

1. a column annotated with a group called "sample-key",
2. values of this *sample-key* column must match the column/sample names of the primary table,
3. one or more additional columns from which covariate values are extracted.

Figure 2.9 shows a simple covariate table with two columns: the `SampleName` column is marked as the *sample-key*. The `Age` column provides the age covariate values, for each sample identified by `SampleName`.

```
Table AgeAnnotation.tsv...
File Path
${org.campagnelab.metaR.home}/data/AgeAnnotation.t
Columns
  SampleName: string [ sample-key ]
  Age: numeric
```

Figure 2.9: **Sample Covariate Table.** A covariate table must have a column annotated with the `sample-key` group, whose values are the sample names of the table that will be annotated with the Covariate table. The other columns hold the values that will be associated to each sample when they are selected.

A covariate table can be associated to a column group by pressing  at the end of the group in the editor or by using the intention shown in Figure 2.10. The annotation added to the group allows to refer to a covariate table in the current model and then select a column from that table with the covariate values (Figure 2.11).

2.9 Table Viewer Tool

The TableViewer Tool was introduced in MetaR version 1.3.

The content of a Table can be inspected with the Table Viewer Tool distributed with MetaR. The tool adds to the MPS interface the capabilities to load the table's content and show it in a graphical context. Wherever a table name appears (in a Table node or in an Analysis script, see Chapter 3), the tool can be opened to see the rows and columns of that table along with their values. Figure 2.12 shows how to activate the tool on a Table node.

Column Groups and Usages

Define Usages:

LPS
ID
heatmap
ignore
age

Define Groups:

LPS=YES used for LPS heatmap
LPS=NO used for LPS heatmap
ID used for ID
sample-key used for << ... >>
counts used for << ... >>
age used for age

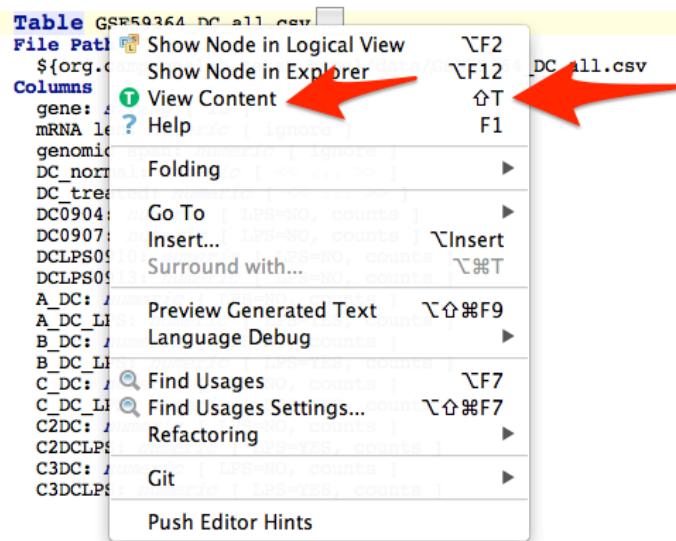

```
counts used for << ... >>
age used for age [ read values from ] use covariate <no_useCovariate>
ignore used for << ... >>
```

The screenshot shows a code editor with a tooltip over the 'use covariate' field. The tooltip lists two tables: 'AgeAnnotation.tsv Table (Demo_with_continuous_data)' and 'SimulatedData.tsv Table (Demo_with_continuous_data)'. Both entries have a small green circular icon with a white letter 'T' next to them.

Figure 2.10: Intention to Add a Covariate Table Use this intention when the values of the Age covariate are provided by in a secondary table: the covariate table.

Figure 2.11: Column Group Annotation Using auto-completion (**ctrl** + **space**) in the no table field, all the tables matching the covariate requirements are proposed. Once selected, a similar action can be used in the no_useCovariate field to select a column from that table. Values from that column are matched with the samples when a statement needs to build a linear model.

Figure 2.12: **How to activate the Table Viewer Tool.** The Table Viewer Tool can be activated by right-clicking on the Table and selecting “View Content” from the menu. An alternative way is to put the cursor on the Table node and pressing + .

The first time it is activated, the tool appears at the bottom of the MPS window, as shown in Figure 2.13.

The tool is immediately available for those tables directly loaded from the file system (e.g. Table nodes) and their references. Other Tables become visible after an Analysis script has been run and the content of the table has been created. In this latter case, the tool is available after the first script execution (see Chapter 3). Note that in this case, if the structure and/or content of a table changes, the Analysis script must be executed again before the tool will show the latest table data.

Figure 2.13: The Table Viewer Tool in the MPS UI.

Figure 2.14: Visualization Options for Table Viewer Tool. Different visualization options are available for the Table Viewer Tool. By right clicking on the tool name in the Tool Buttons bar (if not visible, select **View > Tool Buttons** from the MPS menu), a user can explore them and choose the one that best fits a project needs. In our experience, the floating mode or the Docked/Pinned mode with the panel on the right are very effective.

The screenshot shows the MetaR Table Viewer application window. At the top, it displays the table name "MetaR Table Viewer" and the record count "table: GSE59364_DC_all.csv, #records: 29239". Below this, the table content is shown with columns for gene, mRNA len, genomic span, and various DC_ and A_ metrics. The table has 16 columns and approximately 29,000 rows. Red arrows highlight several features: one arrow points to the table name, another to the record count, a third to the column headers indicating they are resizable, and a fourth to the vertical scroll bar on the right side of the table area.

gene	mRNA len	genomic span	DC_normal	DC_low	DC_low_low	DC_low_low_low	DC_low_low_low_low	DC_low_low_low_low_low	A_DC	A_low	B_DC	B_low	C_DC	C_low	C_low_low	C_low_low_low

3 — Analyses

3.1 The MetaR Analysis Root Node

MetaR analyses are represented with an Analysis AST Root node. An analysis often imports one or more tables, performs data transformations and writes a table or generates some plots. You can create as many Analysis root nodes as needed in a model. You create an analysis by right-clicking on a model and selecting [New] > o.c.metar.tables > Analysis. Analysis can exist as direct child of a model, and for this reason is called a root node. Figure 3.1 presents a new Analysis root node.

name

Each analysis has a name. You should name the analysis after creating it. The name you enter will be shown in the Project Tab after the A icon.

statements

An analysis contains a list of statements. You can enter new statements by typing between the curly brackets { }.

To enter a specific statement, you can type the alias of the statement (for instance `import table`). When you have typed a complete alias, the node will be inserted in place

Figure 3.1: New MetaR Analysis <no name>

Analysis Root Node. This { << ... >> figure presents a freshly } created MetaR analysis root node. You can press ↲ over the << ... >> to add Statement nodes to the analysis. Use auto-completion to discover which types of statements are available.

of the alias. Note that there is no actual indication that the text you are typing matches a valid alias. You need to finish typing the full alias before the node is substituted for the alias. The text you type will remain red until the substitution occurs even if the text is matching a valid alias. See Figure 3.3.

The following sections describe the kinds of statements offered by the `MetaR org . campagne lab . MetaR . tables` language. The simplest way to learn which statements are supported by the release of MetaR that you are using is to use auto-completion. Figure 3.2 provides a snapshot of the auto-completion menu when looking for statements to insert in the Analysis statement list.

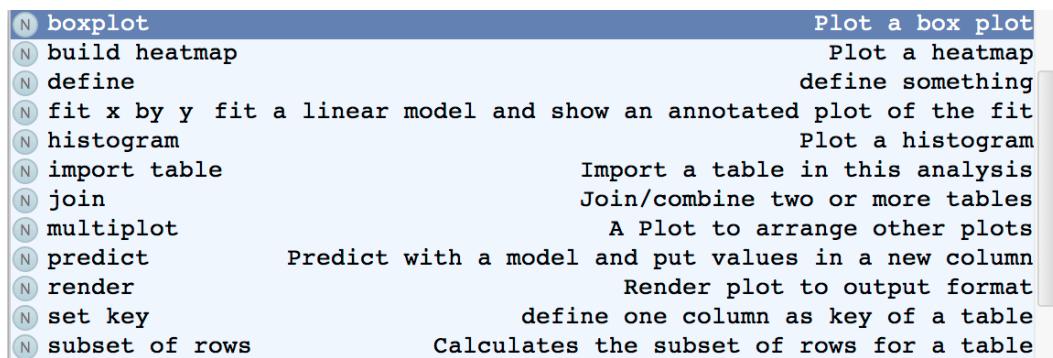

Figure 3.2: **Auto-completion Dialog for Statements.** This dialog is obtained by placing the cursor where a Statement is valid, and pressing `ctrl+space`.

```
Analysis Typing aliases tutorial
{
    import
    import table <no table>
}
```

Figure 3.3: **Typing Statement Aliases.** The user has typed “import” on the third line. This text is a prefix of the import table statement, but is shown in red because the alias is not yet complete. The fourth line shows the import statement which is substituted to the text when the user has just finished typing “import table”, the complete alias of the statement. Note that pressing `enter` immediately after import will create the node if the prefix “import” matches a single type of node in the languages imported in this model.

3.2 Styles

MetaR comes with a styles language that allows to customize the graphical aspects of plots and files generated by statements. A **Style** is represented by a root node in the model with a given name.

To create a Style, right-click on a model in the project tab and select `right-click > New > o.campagnelab.styles > Style`. This will create an empty Style, as shown in Figure 3.4.

```
Style <no name> extends <no extends> {
    << ... >>
}
```

Figure 3.4: **New Style**. A newly created Style AST Root node.

Style nodes are identified by a  icon. A Style is essentially a container for *style items*. Items are well-defined settings that are applied by MetaR during the rendering of a graphical object. Figure 3.5 shows a snapshot of the auto-completion menu when looking for items to add to a style. All possible style items are shown because this style is not yet bound to a specific statement.

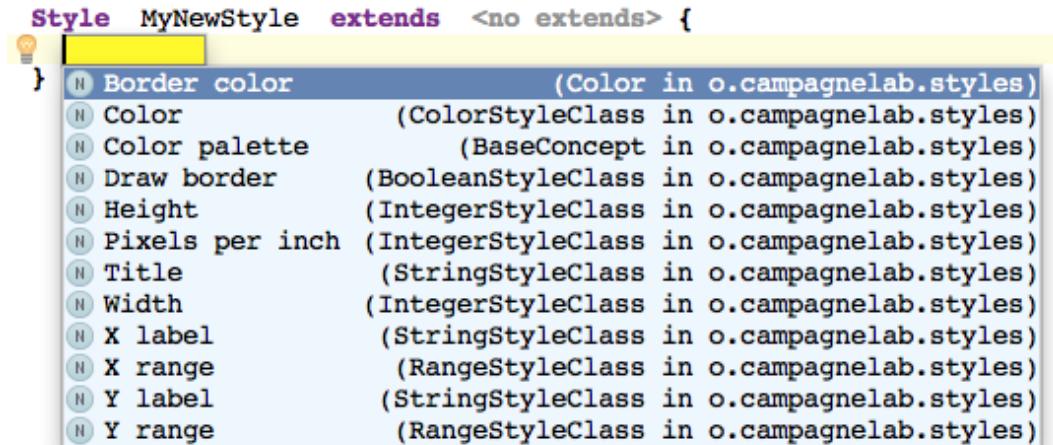

Figure 3.5: **Adding Style Items to a Style**. A Style is a container for Style Items. By using auto-completion `ctrl + space`, style items can be added to the node.

Styles can extend other styles, which provides an ability to modularize appearance. This is useful if you need to build collections of plots, and most plots have a subset of style attributes, but the title of each plot or the X or Y variable changes. You would define the common style attributes in a style, and extend this style each time you need to specialize the style.

3.2.1 Binding Styles to Statements

In order to use a Style, you have to bind a statement to it. There are different approaches you can follow to create this binding and the choice depends on your needs and flexibility.

The simplest way to create a style and bind it to a statement is to use the intention "Create New Style" available on compatible statements as shown in Figure 3.6. This intention will

create a new style and bind it to the statement. This has the advantage that the style items are immediately restricted to only the items compatible with the statement.

Figure 3.6: **Create New Style Intention on Statements.** The user has pressed **option** + **✉** on a statement that can be bound to a style. By selecting the **Create New Style** intention, a new default style is created in the model and bound to the statement.

Once bound to a statement (or more than one), the list of items that can be added to the Style is restricted to the ones compatible with the statement(s). For instance, if the style shown in Figure 3.5 is bound to a statement that uses only a Color Palette and some kind of border drawing, the auto-completion menu will appear as shown in Figure 3.7.

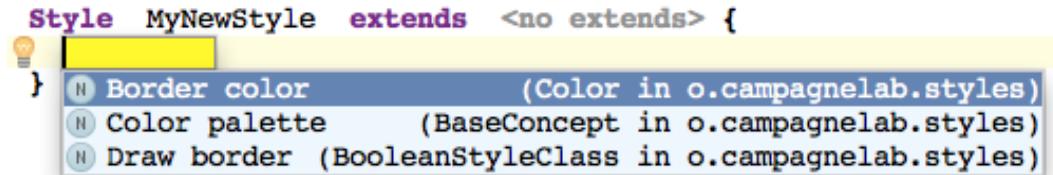

Figure 3.7: **Style with Restricted Items.** A subset of Style Items is displayed in the auto-completion menu when the Style is bound to a statement.

However, styles can be created independently from statements and bound at a later time. In this case, the list of styles visible to a statement in the auto-completion menu is limited to the compatible styles available (see Figure 3.8). A style is defined compatible with a statement if its items or a subset of them are used by the statement.

Figure 3.8: **Styles visible from a Statement.** A statement can be bound only to Styles that define items compatible with the statement.

A library of Styles could be created and reused across multiple Statements, Analyses or even Models. The capability to extends other Styles promotes reuse, reduces redundancies and allows to keep the number of Styles in a model at a minimum.

Figure 3.9: **New Write Statement.** Use this statement to write the content of a table to a file.

3.3 Working with Tables

3.3.1 Import Table

The `import table` statement makes it possible to import a table, defined in the model, into the analysis. The columns of the imported table will become visible to the statements that follow the import. You can create an import table statement by typing the alias `import table` on an empty line of Analysis. Once you have bound the reference to a table, the import statement will look like this: `import table SomeData`. The name in green is the name of the table the statement imports. See Section 2.2 to learn how to create a Table Root node.

table

The table attribute is a reference to an AST root node. You can set this reference by typing the name of the table you wish to import, or by using auto-completion `ctrl + space` to locate the table AST root node.

3.3.2 Write Table

MetaR analyses can create new tables. You can write the data in these tables to a file using the `write` statement (see Figure 3.9 for a new write statement). The write statement has two attributes: `table` and `filename`.

table

This reference should be set to the table that you want to write to a file.

output

The output should be set to a filename where you want the data contained in the table to be written. Notice that `output` has a button to let you select the output filename.

3.3.3 Identify a Set of Columns

Several types of statements require the user to select one or more columns of a table. MetaR provides several ways to select a set of columns.

- You can use the `columns` node to identify a set of columns.
- You can use the `group` node to name a single group, and identify all columns annotated with this group.
- You can use the `groups` node to name a set of groups, and identify all columns annotated with any of these groups.

Each strategy identifies a set of columns, which may contain one or more columns.

```
define Set of IDs <no name> {
    << ... >>
}
```

```
define Set of IDs data1 {
    a b c d e f g h i j k d5 d6 d7
}
```

Figure 3.10: **New Set of Ids Statement.** Use this statement to define a custom set of ids.

Figure 3.11: **Example of a user defined Sets of Ids.** The set contains 14 elements with IDS named a-d7.

3.4 Define Sets of Ids

You can use this statement (alias `define Sets of Ids`) to define a custom set of ids. Figure 3.10 shows a new `define Sets of Ids` statement. Sets of ids can be used draw Venn diagrams (see Section 3.7.5), or to select rows of tables with the `subset` statement (see Section 3.5). To create a new set, use the `define` statement and choose `set of ids` with auto-completion.

name

The set of ids must have a name. The name is used to refer to this set of ids in other parts of the analysis.

ids

By pressing  with the cursor over the « ... » attribute you can add a new id in your set. To add another id, you just have to press again . Figure 3.11 shows an example of `Sets of Ids`.

3.5 Subset Rows

You can use this statement (alias `subset rows`) to filter a table and produce a new table with a subset of the rows of the input table. Figure 3.12 shows a new `subset rows` statement.

```
subset rows <no table> filter how? -> subset
{
    import table GSE59364_DC_all.csv
    define Set of IDs GeneList {
        MAPK PSEN1
    }
    subset rows GSE59364_DC_all.csv with IDs keep rows matching any ID in GeneList -> for geneslist
    subset rows GSE59364_DC_all.csv when true: $(genomic span) > 20000 -> genomic span>2000
}
```

Figure 3.12: **New Subset Rows Statement.** Use this statement to filter the rows of a table.

Figure 3.13: **Subset Rows Examples.** This figure illustrates the two alternatives available for filtering rows: by expression (with `when true:`, or with a set of ID values).

table

The input table reference must be set to a table. The table must be either imported or produced by another statement.

filter

The filter determines which rows are kept. Use auto-completion to select one of the alternatives:

1. `when true:` will keep a row when the boolean expression following `when true:` evaluates to `true`.
2. `with IDs` will keep a row when the value of the column marked with group ID exists in the list provided as an argument. See the `define` statement to create a list of IDs in Section 3.4.

subset

The output table is called subset by default. Feel free to rename this table to better match the data in it.

3.5.1 Example

Figure 3.14 presents examples of subset row statements.

```
{
  import table GSE59364_DC_all.csv
  define Set of IDs GeneList {
    MAPK PSEN1
  }
  subset rows GSE59364_DC_all.csv with IDs keep rows matching any ID in GeneList -> for geneslist
  subset rows GSE59364_DC_all.csv when true: $(genomic span) > 20000 -> genomic span>2000
}
```

Figure 3.14: **Subset Rows Examples.** This figure illustrates the two alternatives available for filtering rows: by expression (with `when true:`, or with a set of ID values).

3.5.2 Boolean Expressions

One form of the subset rows statement accepts a boolean expression to determine which rows to keep. Boolean expression have one of two values: true or false, and can be constructed by comparing values with an operator. The following operators are supported by MetaR:

- `$(column)` The value operator evaluates to the value of the column in the row currently considered.
- `expr1 == expr2` true when `expr1` evaluates to the same value as `expr2`.
- `expr1 != expr2` true when `expr1` does not evaluate to the same value as `expr2`.
- `expr1 | expr2` true when `expr1` is true or `expr2` is true (boolean or, either one of `expr1` or `expr2` needs to be true for the result to be true).
- `expr1 & expr2` true when `expr1` is true and `expr2` is true (boolean and, both `expr1` and `expr2` must be true for the result to be true).
- `expr1 < expr2` true when `expr1` evaluates to a value less than `expr2`.
- `expr1 > expr2` true when `expr1` evaluates to a value greater than `expr2`.

`join (<no_table>) by <no_name> -> <no_name>`

Figure 3.15: **New Join Statement.** Use this statement to join two or more tables into one.

- `expr1 <= expr2` true when `expr1` evaluates to a value less or equal than `expr2`.
- `expr1 >= expr2` true when `expr1` evaluates to a value greater or equal than `expr2`.

 MetaR infers the type of the expressions that you enter and will report type errors if the value of some values are not compatible with the test that you perform.

3.6 Join Tables

When you perform data analysis, you often need to combine data from different tables into one. This operation is called table joining. MetaR provides a powerful `join` statement that helps join an arbitrary number of tables. The alias of the statement is `join`. Figure 3.15 presents a newly created `join` statement. `Join` has three attributes: input tables, `by` and output table.

input tables

Use this attribute to enter references to tables you need to join. You can press  with the cursor inside the parentheses to create references to additional input tables (either imported or created in the analysis up to that point).

by

Use the `by` attribute to specify how to join the input tables. Joining tables requires knowing which rows of the input tables go together. This is done by identifying a set of columns whose values must match across rows of the input tables that go together. See Section 3.3.3 to learn how to select groups of columns in MetaR. You can select one of the following joining strategies as value of the `by` attribute:

- **by columns:** The same column name must be defined in all the input tables.
- **by group:** If each table has exactly one column annotated with this group, the names of the columns do not need to be the same. Otherwise, if more than one columns is in the group, their names must match across all the tables.
- **by groups:** Similar to group, but with any ($>=1$) number of groups. Press  to insert new group references.

The group by columns are used to calculate a list of values. When rows of the input tables have the same group by values, they are joined in a single row, and the result put in the destination table.

 The join statement will create new columns if the input tables have columns with the same name. In this case the shared columns are renamed “`colname.TableName`”. Place the cursor on result and look at the column preview in the inspector to see which column names are generated by a given join statement.

result

The output table is called Results by default. Feel free to rename this table to match the content of the destination table. Open the  2: Inspector to see which columns will result from the join. Notice that the column groups are transferred to the columns of the output table.

3.6.1 How Join works

The output table produced by the `join` statement can be very different, depending on the strategy selected to join the input tables and their structure. The statement takes also care to produce unique columns from columns common to all the input tables but not used in the joining strategy. To explain how `join` works we will apply two different strategies to the input tables (named A and B) presented in Figure 3.16 and check the structure and content of the output table.

Table A			Table B			
Gene	Column1[ID]	Column2	Gene	Column2	Column3	Column4[ID]
Ge1	Val1	34	Ge4	1	78	Val1
Ge2	Val2	452	Ge2	3	13	Val3
Ge3	Val3	113	Ge1	4	44	Val4

Figure 3.16: Sample Input Tables for Join Statement.

Do note that the two tables have columns in common (Gene and Column2) and that each table has a column annotated with a group named ID (Column1 in table A, Column4 in table B).

join by column

As first strategy, we join A and B by the column Gene. The results table generated by `join` is shown in Figure 3.17.

Table Results (by Column Gene)					
Gene	Column1	Column2.A	Column2.B	Column3	Column4
Ge1	Val1	34	4	44	Val4
Ge2	Val2	452	3	13	Val3

Figure 3.17: Results Table for Join using by Column Strategy.

If we analyze the structure of the table, we note that:

- there is only one Gene column (the one used for joining)
- Column2, that was present in both the input tables, was split in two columns named Column2.A and Column2.B
- the rest of the columns are the same coming from their respective input tables

Looking at the table's content, we note that:

- rows from input tables with a matching value in the Gene column were merged into a single row.

- all the other columns keep their original value from the source table with respect to the Gene column's value

join by group

Our second strategy is to join A and B by group ID. As shown in Figure 3.16, there are two columns, one in each input table, annotated with such a group and they have different names. The `join` statement is able to work even in this case by matching the values of these two columns. The results table generated by Join is shown in Figure 3.18. Again, let's go over the structure of the table:

- Gene, that was present in both the input tables but this time not used as joining column, was split in two columns named Gene.A and Gene.B
- Column2, that was present in both the input table, was again split in two columns named Column2.A and Column2.B
- the rest of the columns are the same coming from their respective input tables

Table Results (by Group ID)						
Column1	Gene.A	Gene.B	Column2.A	Column2.B	Column3	Column4
Val1	Ge1	Ge4	34	1	78	Val1
Val3	Ge3	Ge2	113	3	13	Val3

Figure 3.18: **Results Table for Join using by Group Strategy.**

Looking at the table's content, we note that:

- rows from input tables with a matching value in Column1 from A and Column4 from B were merged into a single row
- all the other columns keep their original value from the source table with respect to their matching column's value

3.6.2 Example Join

Figure 3.19 presents an example of join statement. The statement joins two tables and creates the Result table. If you open the  Inspector, you will see a preview of the columns for the result table (shown in Figure 3.20).

3.7 Plotting Data

MetaR provides simple plotting capabilities¹. The following types of plots are currently supported:

¹These capabilities are simple, but can be extended very easily by adding new statements to draw other types of visualization. This is a key advantage of using Language Workbench technology.

```
{
  import table GSE59364_DC_all.csv
  import table another Table
  join ( GSE59364_DC_all.csv , another Table ) by group ID -> Results
}
```

Figure 3.19: **Example of Join Statement.**

```

path= /Users/fac2003/R_RESULTS/table_Results_0.tsv  name: Results table.name Results groups= LPS=NO,counts,LPS=YES,ID

DC0907.another Table : numeric [ LPS=NO, counts ]
DC0907.GSE59364_DC_all.csv : numeric [ LPS=NO, counts ]

```

Figure 3.20: **Column Preview for Result Table.** Notice that all these columns were shared across the input tables because their name follows the pattern “colName.tableName”.

Figure 3.21: **New Boxplot** `boxplot` with `<no col>` -> `<no name>` no style Statement.

- boxplot alias `boxplot`
- histogram alias `histogram`
- scatterplot: alias `fit`
- heatmap, alias `heatmap`
- multiplot alias `multiplot`, makes it possible to organize other plots in a matrix of n columns by n rows.

Each type of plot statement will create a plot, identified with the  icon when you are trying to auto-complete a reference to a plot. Plot names are also colored with the same dark blue as the icon.

Generated plots can be customized and refined by binding each statement to a style (see 3.2). A reference to a style is back-colored with the same turquoise color as the  icon.

3.7.1 `boxplot`

Figure 3.21 presents a new boxplot statement.

`columns`

Indicate one or more columns to plot. The values of the columns will be plotted as individual boxplots in the same graph. Press  to define more than one column. Use

auto-completion to locate individual columns from the imported tables, or the tables created by prior statements.

plot

The attribute after `->` is a plot. Enter a name for the boxplot here. Plot names are colored blue to make them easier to recognize.

style

If a style is bound to the box plot (see section 3.2), the statement will use a `ColorPalette` item from the style to draw the plot. A Color Palette is an AST Root Node identified with the 🎨 icon.

MetaR comes with several pre-defined palettes and colors ready for use. Figure shows the auto-completion menu for a `Color Palette` item listing the default palettes available.

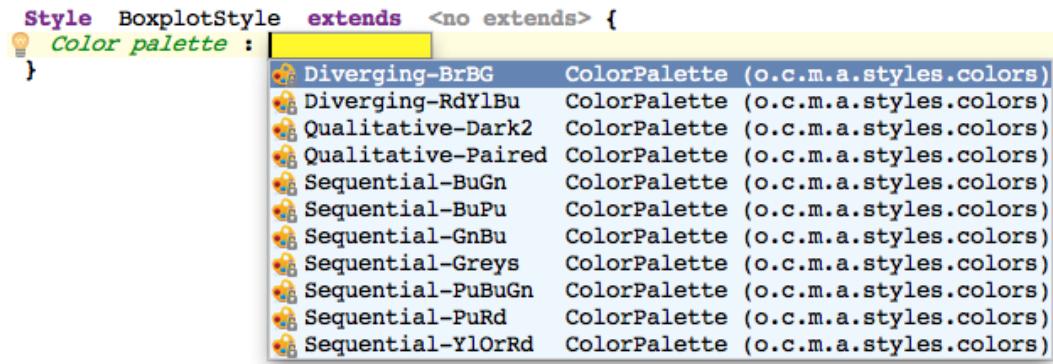

Figure 3.22: Auto-completion menu with default Color Palettes.

You can create a new palette by right-clicking on a model and selecting `New > o.campagnelab.styles > Color Palette`. Colors can be added to a palette and their order will matter in the rendering of the plot. Figure 3.23 shows a Color Palette with some color items and the auto-completion menu listing some of the default colors available.

There are two classes of colors you can use in a palette:

- **Named Colors.** New named Colors can be created by right-clicking on a model and selecting `New > o.campagnelab.styles > Color`. A color is identified by the 💧 icon and its name must be valid in the R language.
- **#RRGGBB Colors.** These colors can be created directly inside the Color Palette by selecting the `#RRGGBB` option in the auto-completion menu for a Color value. The color will be constructed from the combination of the Red, Green and Blue specified in the code.

3.7.2 histogram

Use this statement to plot a histogram of the values of one column.

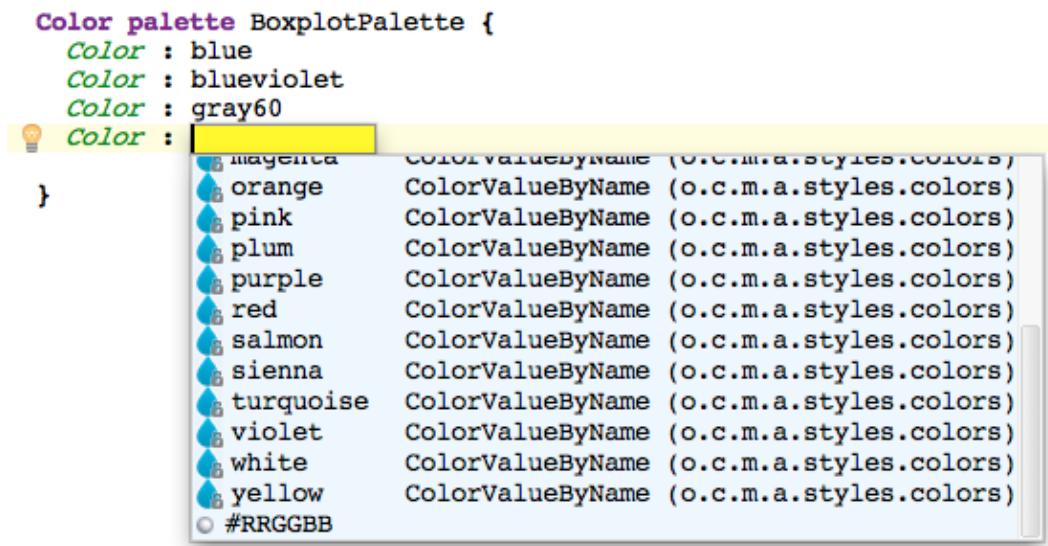

Figure 3.23: **Auto-completion menu showing some default Colors and the ##RRGGBB option.** The auto-completion menu lists the visible Colors and #RRGGBB option. By selecting this latter, you can create a custom color based on the Red Green Blue color components (RGB).

column

Indicate one column to plot a histogram for. Use auto-completion to locate the column from the imported tables, or the tables created by prior statements.

plot

The attribute after -> is a plot. Enter a name for the histogram here. Plot names are colored blue to make them easier to recognize.

style

The statement uses a **ColorPalette** item (see 3.7.1) from the associated style (see section 3.2) to draw the plot.

3.7.3 fit x by y

Use this statement (alias **fit**) to plot a scatter plot of x (one column) vs y (another column). A fit is performed, and the R² adjusted, and P-value corresponding to the linear regression is shown on the plot. Figure 3.24 presents a new **fit** statement.

```
fit <no_col> by <no_col> with table <no_table> -> <no_name> no style
```

Figure 3.24: **New Fit X by Y.**

x, y

Indicate which columns should be plotted. Use auto-completion to locate the x and y columns from the imported tables, or the tables created by prior statements.

plot

The attribute after -> is a plot. Enter a name for the scatterplot here. Plot names are colored blue to make them easier to recognize.

style

The fit statement uses the following items from the associated style (see section 3.2) to customize the scatterplot:

- **Title**. The main title on top of the plot.
- **X label**. A title for the x axis.
- **Y label**. A title for the y axis.
- **X range**. Range of values for the x axis.
- **Y range**. Range of values for the y axis.
- **Width**. Width in pixels of the output image with the plot.
- **Height**. Height in pixels of the output image with the plot.

3.7.4 heatmap

Heatmaps are frequently used to visualize high-throughput data [Cook2007]. Use the heatmap statement (alias heatmap) to construct a heatmap plot. Figure 3.25 presents a new heatmap statement.

```
heatmap with <no_table> select data by<no dataSelection>-> <no_name> no style [ ]
```

Figure 3.25: **New Build Heatmap**. Notice the intention “Add Annotations” attached to the statement. You can use this intention to further customize the heatmap.

table

Specify the table that contains the data that will be used to draw the heatmap. Note that the table must meet certain conditions. An error message will be displayed if these conditions are not met:

- Some columns of the table must be annotated with at least one group whose usage is “heatmap”. Such columns are used to provide data values for the heatmap. If you don’t have a heatmap usage, just create one and add it to the groups you would like to include on the heatmap.
- The columns of the table must be annotated with groups and group usages to make it possible for you to use these group usages to construct a legend.

select data by

Use this attribute to customize the set of columns to plot on the heatmap. See Section 3.3.3 to learn how to select a set of columns.

plot

The `<no name>` attribute listed after `->` makes it possible to name the plot that will hold the heatmap. Use any name you like. This name will be used to refer to the heatmap plot, for instance if you wish to assemble panels of different heatmaps into one figure.

style

The statement uses the following items from the associated style (see section 3.2) to customize the heatmap:

- **Color palette.** The colors to use in the heat map (see 3.7.1).
- **Draw border.** A boolean value to enable or disable borders in the heatmap. A value of `true` will draw a border. A value of `false` will not. By default, borders are enabled.
- **Border color.** The color to use for the border (see section 3.7.1 to check out how to create/refer to colors). If not set, the default color is `grey60`.

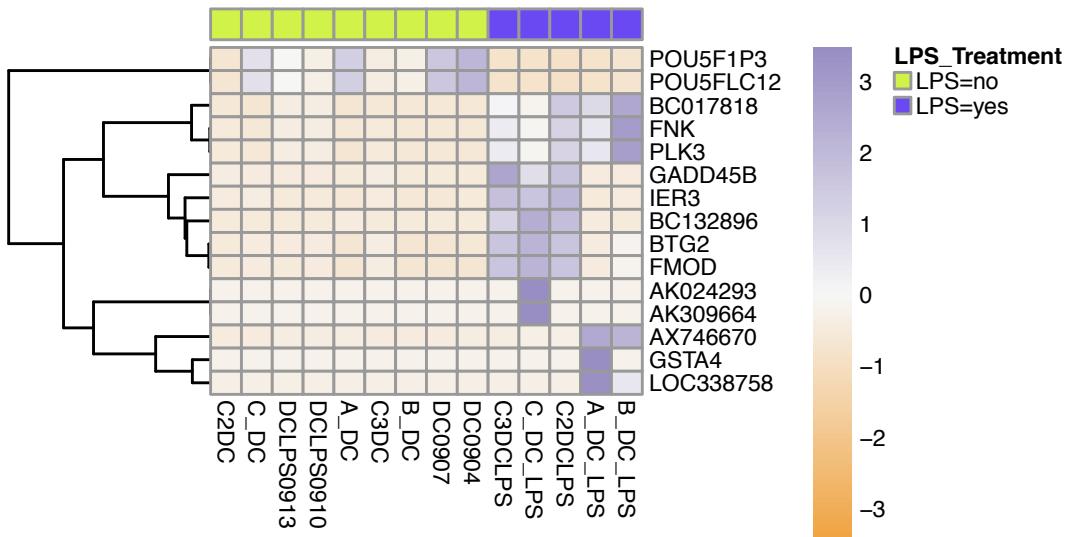

Figure 3.26: Example of Heatmap Plot. This heatmap has been customized with annotations. The `LPS_Treatment` group usage is shown in the legend, with two groups: `LPS=yes` and `LPS=no`. The values plotted have been scaled by rows, and the rows clustered. Data are from <http://www.ncbi.nlm.nih.gov/geo/query/acc.cgi?acc=GSE59364>.

annotations

You can use the “Attach Annotations” intention (💡) when the cursor is on top of `heatmap` to customize heatmap annotations. Figure 3.27 shows a heatmap statement with annotations.

annotate with these groups. You can use this attribute to select usage names that should be listed in the heatmap legend. Listing a group usage will annotate each column of data with the group that is associated to the usage.

```
heatmap with GSE59364_DC_all.csvselect data by columns: A_DC B_DC -> heatmap HeatmapStyle [
  annotate with these groups:<< ... >>
  scale values:<no scaling>
  cluster columns:false cluster rows:false
]
```

Figure 3.27: **Build Heatmap With Annotations.** Annotations are shown after you have triggered the “Add Annotations” intention.

scale values. You can choose to scale values by column or by row. Scaling will make differences easier to see by using colors more effectively.

cluster columns: You can choose to cluster by colors or by rows by changing the boolean values accordingly.

Example

Figure 3.26 presents a heatmap constructed with the build heatmap statement, using annotations and row clustering.

3.7.5 Venn diagram

The Venn diagrams were introduced in MetaR version 1.3.

Venn diagrams are useful to show how many elements exist in various intersections among sets of elements [venn1880diagrammatic]. Use the Venn diagram statement (alias venn) to draw a Venn diagram plot. Figure 3.28 presents a new Venn diagram statement.

```
Venn diagram of { set <no name> from set of ids <no oneSetOfIds> with default color } -> <no name>
```

Figure 3.28: **New Venn Diagram.** Up to five sets can be shown on a Venn diagram. The name of each set will be shown on the Venn diagram plot.

```
Venn diagram of { set set1 from set of ids data1 with color : aquamarine
  set <no name> from table <no table> when true: <expression> with default color } -> <no name>
```

Figure 3.29: **Sets type of Venn Diagram.** Here you can see the two types of sets which can be used for a Venn diagram: a user defined set and a set from an annotated table.

name

The name attribute can be specified immediately after the set keyword. A set must have a name, which will be shown on the Venn diagram to identify this particular set.

set

Up to five sets can be shown on a Venn diagram. The data set are divided in two types:

ids from a user defined set contains only one attribute: `set of ids`. The `set of ids` attribute must refer to a user defined set. see Section 3.4 to learn how to define new sets of ids.

ids from an annotated table contains two attributes:

- `table`. This attribute must refer to a table annotated with an "*ID*" group on a column that will provide identifiers for the set elements.
- `expression`. This expression defines how to select rows of the table to extract ids for the set. The expression must return true when a row of the table is part of the set. When this is the case, the value of the column marked with the ID group is extracted and added to the elements of the set.

Notice that you can turn one type of ids into the other with auto-completion. place the cursor on top of the `set` keyword and invoke `ctrl+SPACE` to switch the type of set. Notice that the name and color attributes, if defined, are preserved.

color

The `default color` attribute listed after `with` makes it possible to customize the color used to draw the set on the Venn diagram. By using auto-completion, a menu listing the default colors available will appear. Default colors will be used for each set where a color has not been defined.

plot

The `<no name>` attribute listed after `->` makes it possible to name the plot that will hold the Venn diagram. Use any name you like. This name will be used to refer to the Venn diagram plot.

Example

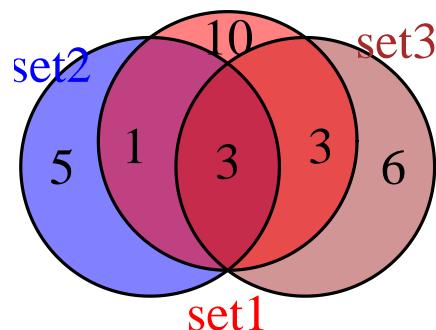

Figure 3.30: Example of Venn Diagram with Three Sets.

Figure 3.30 presents an example of a Venn Diagram showing three sets.

3.7.6 multiplot

This statement (alias `multiplot`) makes it possible to assemble a plot as a matrix of $m \times n$ plots. This is convenient if you would like to create a figure from panels of individual plots. In addition, multiplot provides a preview of the multi-panel plot that you can turn on and off at the click of a button. Figure 3.31 presents a new Multiplot.

```
multiplot -> <no name> [ <no numColumns> cols x <no numRows> rows ] Preview
<<emptyTable>>
```

Figure 3.31: New **Multiplot Statement**. Click on the Preview/Hide Preview button to toggle the plot preview.

plot

The plot name is shown immediately after `->` (initially `<no name>`). Name the mutliplot to be able to refer to it from other statements (such as `render` to make a PDF from it).

m cols x n rows

Define the number of columns and rows that you wish the multiplot to have. The product of m and n determines how many plot references must be filled in to construct the multiplot.

Preview/Hide Preview

These buttons will make it possible to preview/ hide the preview for the multiplot. Note that a preview is only available after you have run the analysis. If you don't see the image being refreshed after running the script, remember to hide the preview and show it again to refresh.

plot references

After you set the number of columns and rows, you need to link $m \times n$ references to plots that you have already constructed. Do this in `table` attribute (shown as `«emptyTable»` initially).

Multiplot Example

Figure 3.32 presents an example of `multiplot`.

3.7.7 render

This statement (alias `render`) makes it possible to save a plot or a multiplot in a local file according to a selected output format and style. Figure 3.33 presents a new Render.

plot

The `<no plot>` attribute listed after the alias allows you to select the plot or multiplot to render.

rendering format

The rendering format is the format in which the plot will be stored on the file system. The current version of MetaR allows to use only PDF as format.

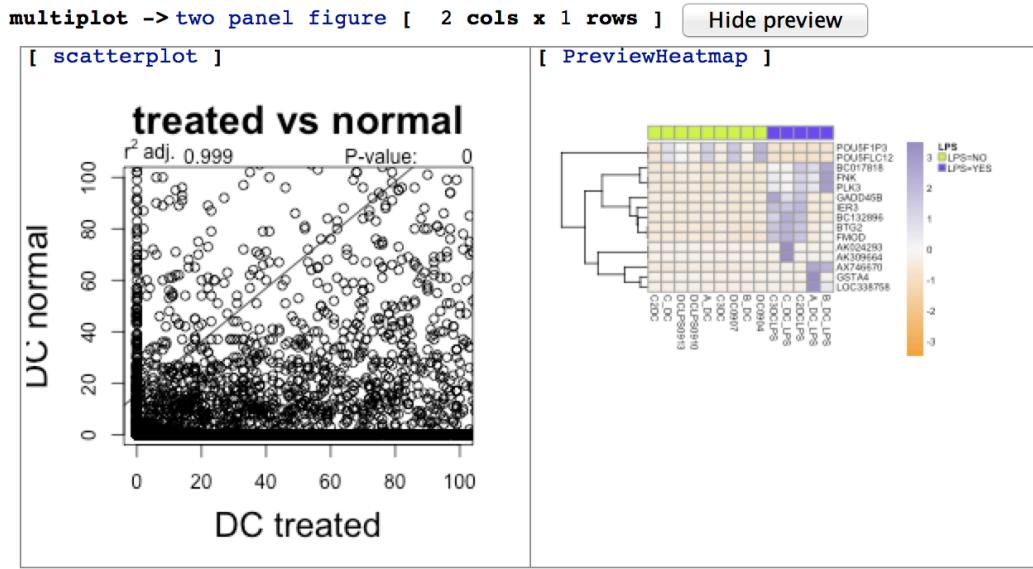

Figure 3.32: **Example of Multiplot.** This example shows a multiplot composed of two columns and one row. In the preview, a fit x by y plot is shown on the left, and a heatmap on the right.

```
render <no_plot> as <no> named "<no_path>" ... no style
```

Figure 3.33: **New Render Statement.**

path

The <no_path> attribute has to be set to a filename where you want the rendering is stored. Its extension must be compatible with the selected format (e.g. ".pdf" for PDF). If only a filename is specified

style

4 — Docker Integration

The integration with Docker helps with the reproducibility of your analyses. Installing packages with R does not make it possible to specify exactly the version of the package that you need for an analysis. While it is possible to always install the latest version of a package, the behavior of some packages will change over time. For this reason, it is useful to build snapshots of the R packages used during analysis and report the version number of the snapshot.

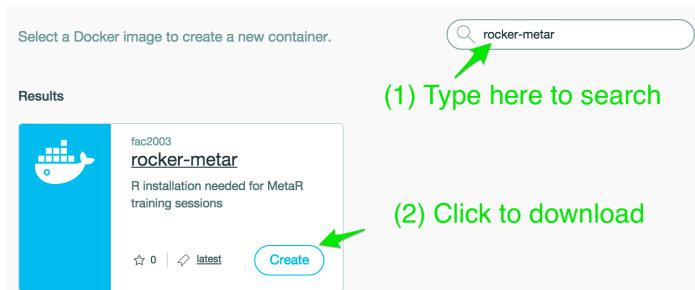

4.1 Pre-requisites

You will need a working docker installation on your machine before you can run MetaR analyses with Docker.

4.1.1 Mac OS

Mac users will find it convenient to download and install Kitematic (<https://kitematic.com/>). After you unzip Kitematic, move the application to /Applications and start it. Wait until the virtual machine downloads and starts. When kitematic is ready, use the search box to locate the `rocker-metar` image (see Figure 4.1 for instructions).

Figure 4.1: Download the MetaR Docker Image. Follow steps to locate the MetaR Docker image.

4.1.2 Other Platforms

Other users should refer to documented installation steps for their platform (see <http://docs.docker.com/installation/>).

4.2 Configuring Docker

Docker integration can be configured using the MPS Preferences. Open Preferences (Setting on Windows) and locate the Docker configuration (use the search box with the docker keyword). You will be presented with the following dialog shown in Figure 4.2.

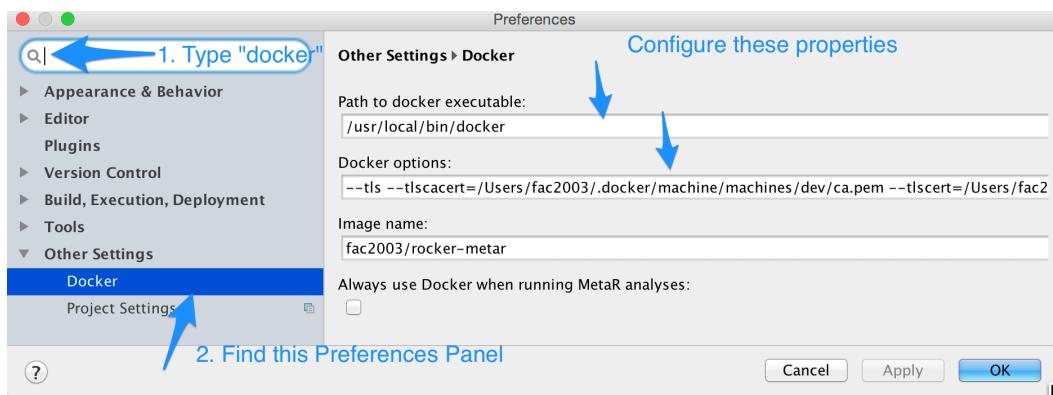

Figure 4.2: **Docker Configuration Dialog.** This dialog is available under MPS Preferences/Settings.

path to docker executable

This field must provide a path to a valid docker executable. On linux, try `which docker` in the shell. On Mac, if you installed Kitematic, open the application and start the terminal with the `File > Open Docker Command > Line Terminal Window`. In the window, type `which docker` and copy the location to the field.

docker options

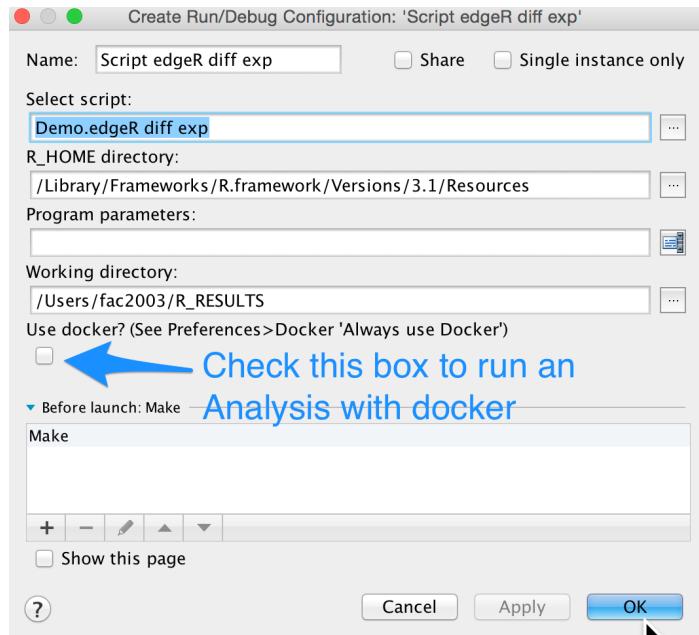

These are the options necessary to connect to the docker server. On Mac, if you installed Kitematic, open the application and start the terminal with the `File > Open Docker Command > Line Terminal Window`. In the window, type `echo 'docker-machine config'` and copy the line printed to the field.

image name

This is the name of the docker image that you wish to use with MetaR. Keep the default, or enter a customized image name here. Customizing the image is useful if you need to install additional packages than the ones we use during our training sessions. If you create a new image, make sure you use `fac2003/rocker-metar` in the FROM field. Images that do not build on `fac2003/rocker-metar` are not supported at this time.

Figure 4.3: **Run With Docker.** Right-click on an Analysis and do `Create <analysis name>`.

You will be presented with the Run Configuration customization dialog. Check the box to run with docker. Disable the check-box to run directly against the R installation on your computer (this behavior was the default prior for MetaR 1.3-).

R Note that you can specify an image tag/version number. Append a colon (:) and the tag after the image name. For instance, use `fac2003/rocker-metar:1.3.1` to run the `rocker-metar` image packaged with MetaR 1.3.1.

R Note that specifying a tag is a good idea if you need to reproduce exactly an analysis in the future. Omitting the tag will always get the latest version of the image, which may change over time.

always use docker

This checkbox can be used to force the use of Docker by default when running an Analysis. This is convenient if you know that your configuration is correct and want to run all analyses with docker.

4.3 Running with Docker

When docker is successfully configured, you can specify to use the docker image when running a MetaR analysis. See instructions in Figure 4.3 to see how to configure running inside a Docker container.

5 — EdgeR

5.1 Understanding Language Composition

The EdgeR language (`org.campagnelab.metaR.edgeR`) has been developed as a illustration of language composition with MetaR. When you import the `org.campagnelab.metaR` devkit into MPS, you are able to create analyses and the statements described in the previous Chapter. If you tried to enter the `edgeR` alias, the error shown in Figure 5.1 would appear. The reason is that by default, MetaR does not provide an EdgeR statement.

If you now also import the `org.campagnelab.metaR.edgeR` language (use `⌘+L` and import the `edgeR` language), you will be able to use the `edgeR` statement. A new EdgeR statement is shown in Figure 5.2. Adding the EdgeR language to MetaR contributes a new kind of Analysis statement, which becomes available through auto-completion. From a user point of view, importing languages is all that is required to extend MetaR with new language constructs. This new statement can be configured by the user and will generate R code together with the other statements. This happens seamlessly and requires no other configuration than declaring that the model uses another language.

Figure 5.1: Error When Typing the EdgeR Alias.
The EdgeR statement is not yet defined.

```
edgeR counts= <no table> model: ~ 0
comparing <no name> -> <no name> (normalize with common dispersion estimations )
```

Figure 5.2: New EdgeR Statement. A new EdgeR statement created after you have added the `org.campagnelab.metaR.edgeR` language to the model's MPS Used Languages.

5.2 The edgeR Statement

The edgeR statement performs tests of differential expression using read counts contained in a table of data. The statement has the following attributes.

counts table

The table must contain columns annotated with the “counts” group. Bind this table reference to a table that contains non-normalized read counts.

model

You can use the model attribute to enter a linear model. EdgeR will use this model to model the mean and variance of the data. You can enter a linear model by typing + followed by the name of a group usage attached to the counts table. Repeat to add multiple factors to the model.

EdgeR will use an exact test when the model has one factor, but will use a Generalized Linear Model (GLM) when the model has more than one factor. This is handled transparently.

comparing

The comparing attribute makes it possible to define the statistics that should be tested for difference with zero. After you have defined a model with several factors (corresponding to group usage), the factor levels (corresponding to group names) will be offered for auto-completion. The factor level name stands for the average of the columns annotated with the group. See Figure 5.3 for an example.

normalize with

EdgeR supports three types of normalization methods, which estimate variance/dispersion in different ways:

- common dispersion
- trended dispersion
- tagwise dispersion

Place the cursor on the keyword following normalize with and use auto-completion to switch from one type of normalization method to another. The the EdgeR Bioconductor documentation <http://www.bioconductor.org/packages/release/bioc/html/edgeR.html> for details about these approaches.

5.3 Example

Figure 5.3 presents an example where the edgeR statement is configured with a model (one factor: LPS) to call differences between columns labeled with the groups LPS=YES and LPS=NO.

```
edgeR counts= filtered model: ~ 0 + LPS
comparing LPS=YES - LPS=NO -> Results (normalize with tagwise dispersion )
```

Figure 5.3: **EdgeR Example.**

6 — Limma Voom

 Limma Voom is a statement introduced in MetaR 1.3.

6.1 Overview

The Limma Voom statement makes it possible to use the Limma R package and the Limma Voom adjustment to analyze RNA-Seq data with Limma. Similarly to EdgeR, the language that provides the Limma Voom statement must be added to the model where you plan to use the statement in analysis. The name of the language is *org.campagnelab.metar.limma*. Note that this language depends on *org.campagnelab.metar:models*, which should also be imported.

6.2 The Limma Voom Statement

The `limma voom` statement performs tests of differential expression using read counts contained in a table of data. The statement has the following attributes. Figure 6.1 presents a newly created Limma Voom statement.

```
limma voom counts= <no table> model: ~ 0
comparing <no name> -> <no name>
```

Figure 6.1: New Limma Voom Statement.

counts table

The table must contain columns annotated with the “counts” group. Bind this table reference to a table that contains non-normalized read counts.

model

You can use the model attribute to enter a linear model. Limma Voom will use this model to model the mean and variance of the data. You can enter a linear model by typing + followed by the name of a group usage attached to the counts table. Repeat to add multiple factors to the model.

comparing

The comparing attribute makes it possible to define the statistics that should be tested for difference with zero. After you have defined a model with several factors (corresponding to group usage), the factor levels (corresponding to group names) will be offered for auto-completion. The factor level name stands for the average of the columns annotated with the group. See Figure 6.2 for an example.

adjusted counts

This attribute is exposed under the Inspector Tab(). It takes a boolean value: either true or false. When true, the limma voom statement will produce a table of adjusted counts. Data in this table is adjusted to remove the effect of covariates described in the model, but not used in the comparing attribute. This is useful to remove the effect of batches, or other cofactors expected to affect expression. Adjusted counts are implemented with the Limma removeBatches function.

6.3 Example

Figure 6.2 presents an example where the Limma Voom statement configured with a model (one factor: LPS) to call differences between columns labeled with the groups LPS=YES and LPS=NO.

```
limma voom counts= filtered model: ~ 0 + LPS
    comparing LPS=NO - LPS=YES -> results adjusted counts: adjusted
```

Figure 6.2: **Limma Voom Example.** This example would generate an error because the model needs more than LPS to adjust for covariates. This is implied in the use of **adjusted counts**.

7 — Biomart

7.1 Overview

The BioMart project develops software and data services that are made available to the international scientific community. Users of MetaR can access data Marts provided by BioMart, providing access to a wide range of research data . Similarly to EdgeR and Limma, BioMart support is provided in a MetaR language extension. This means that in order to access BioMart with MetaR, you first need to add the Biomart language to the model where you create the analysis. To do so, you can press **Ctrl+L** and add language `org.campagnelab.metar.biomart`. After adding the biomart language to the model, you can create `query biomart` statements, described in the following sections.

7.2 The Biomart Statement

The `query biomart` statement makes it possible to interactively specify which data should be retrieved from a mart (using attributes and filters). Data downloaded from Biomart will be stored in a new table. Figure 7.1 presents a newly created Biomart statement. The `query biomart` statement has the following parameters.

- database
- dataset
- attributes
- filters

```
query biomart database select a database and dataset select a dataset
  get attributes << ... >>
  filters << ... >>
-> resultFromBioMart
```

Figure 7.1: New Query Biomart Statement.

database

The first time you will create the `query biomart` statement, you will automatically download the available Biomart databases. To choose one of them, go to the text *select a database*. Then, press `ctrl+space` to display all available databases. Select one of them by pressing `enter`.

dataset

Once a database is selected, you need to choose a dataset. To choose one, press `ctrl+space` to display all available datasets, on the text *select a dataset*. Then, press `enter`, to select your dataset.

A dataset as two childrens:

- attributes, which will be the column of your result table.
- filters, which allow you to restrict your result table for some criteria.

R Sometimes, a dataset cannot be associated with attributes or filters. In this case, in the auto completion menu for both attributes and filters will display the message "*No available filter or attributes in this dataset*". The selected dataset is no more available in Biomart. You must change your dataset or database.

attributes

Attributes are columns of your result table. Figure 7.2 presents a new biomart attribute. An attribute has three parameters:

- attribute, a column you want to retrieve on your result table. Press `ctrl+space` to display the available column.
- type, the value type of the attribute. It exist 3 value types boolean, numeric and string (*by default*). To change the type, press `ctrl+space`.
- column group, an attribute can have a group such as "ID". The user can display the autocompletion menu by pressing `ctrl+space`. Group must be defined in the Column Group Container to be added to the result table.

R You must select at least one column to run your query biomart Statement.

```
query biomart database ENSEMBL GENES 79 (SANGER UK)and dataset Mus musculus genes (GRCm38.p3
get attributes<no attribute> of types string with column group annotation select a group
filters << ... >>
-> resultFromBioMart
```

Figure 7.2: **Select an attribute in a biomart dataset.** explain the figure and how works this part

Filters

Filters allow you to restrict your result for some criteria. this criteria are link directly to your dataset. Figure 7.3 presents a new biomart filter. It exist four filter categories:

- boolean, you want to retrieve or excluded only data which have an information. *for example, if this gene has or no a Mirbase ID.*

- text, you have to enter a text in this area. the Query will return only informations which match your text. *For example a specific GO term.*
- list, you need to choose a value from a define biomart list. *For example a specific chromosome in a specie.*
- id list, you can restrict your results from a set of ids. This ids can come from a set of ids define before the statement, or directly from an annotated table with an (ID group).

```
query biomart database ENSEMBL_GENES 79 (SANGER UK)and dataset Mus_musculus_genes (GRCm38.p3
get attributesEnsembl Gene ID from featureof types string with column group annotationID
filters no filter <no filterWith>
-> resultFromBioMart
```

Figure 7.3: **New Biomart Filter.** explain the figure more

table

The future table where your result will be stored. Column annotation is display under the Inspector Tab ( 2: Inspector).

7.3 Example

Overview

- Create a new Language
- Create a new Language Concept
- Define the Editor
- Generate R Code
- Using the New Language
- Git Repository

8 — Extending MetaR

8.1 Overview

Because MetaR is developed in the MPS language workbench, you can use language composition as a way to extend the MetaR language. In this Chapter, we provide a very simple example to illustrate how to extend MetaR through language composition.

Let's assume that you have just learned about the `heatmap.2` function provided in the `gplots` R package. You wish to use this function to create heatmaps with MetaR. To achieve this, you would follow the following steps:

1. Create a new MPS Language.
2. Create a `Heatmap.2` language concept in the Structure Aspect of the language (see [`campagne2014mps`]).
3. Customize the Generator to transform instances of the `Heatmap.2` into R code.

8.2 Create a new Language

Let's create a new language. To do this, select the project and do `right-click > New > Language`. Name the language something like `your.domain.heatmap`. When the language has been created, select its name under the Project Tab and adjust Dependencies to include `org.campagnelab.metaR.tables`. Set the Scope to Extends (this will allow statements of this new language to extend concepts of `org.campagnelab.metaR.tables`).

8.3 Create a new Language Concept

Select the Structure Aspect of the `your.domain.heatmap` language and do `right-click > New > Concept`.¹ Name the concept `Heatmap2`. Define the extends clause to be `Statement` (from language `org.campagnelab.metaR.tables`). The resulting concept should appear as shown in Figure 8.1.

¹You can create a new language in an existing project, or use the New Project Dialog to create a Project with type “Language”.

concept alias

Define the alias of the concept. Use `heatmap2`. An instance of the concept will be created when you type this keyword in the editor.

reference to a table

To plot a heatmap, we will take data from a MetaR table. This can be achieved by adding a `TableRef` child to the `Heatmap2` concept. Set the cardinality to exactly one child ([1]).

heatmap produces a plot

The `heatmap2` statement will produce a plot, so you need to add a child of type `Plot`. You may call this child ‘plot’ for simplicity. Set the cardinality to exactly one child ([1]).

```

concept Heatmap2 extends Statement
implements <none>

instance can be root: false
alias: heatmap2
short description: <no short description>

properties:
<< ... >>

children:
<< ... >>

references:
<< ... >>

```

Figure 8.1: **Heatmap2 Concept.** The `Heatmap2` concept extends `Statement`. When the language is composed with MetaR, `Heatmap2` will become available for auto-completion whenever a MetaR Statement can be used.

Figure 8.2 presents the completed concept after adding alias, table and plot.

8.4 Define the Editor

An MPS editor customizes how a node appears in the editor. Create an editor for `Heatmap2` (see [campagne2014mps]) and define its content as shown in Figure 8.3.

8.5 Generate R Code

In order to generate the statement to R code, we will use the MPS Generator aspect.

In the first step, we create a reduction rule, see Figure 8.4 and [campagne2014mps] (Generator Aspect chapter). The rule indicates that nodes of the `Heatmap2` concept will be transformed with the `reduce_Heatmap2` template. The template was created using

```
concept Heatmap2 extends Statement
    implements <none>

    instance can be root: false
    alias: heatmap2
    short description: <no short description>

    properties:
    << ... >>

    children:
    table : TableRef[1]
    plot  : Plot[1]

    references:
    << ... >>
```

Figure 8.2: **Complete Heatmap2 Concept.** This figure shows the completed Heatmap2 concept with an alias and children for table and plot.

Figure 8.3: **Editor of the <default> editor for concept Heatmap2 Statement.** Notice how the editor simply shows the name of the statement, delegates to the TableRef editor to render the table reference, and delegates to the Plot editor to show the plot child.

```
<default> editor for concept Heatmap2
node cell layout:
[- heatmap2 % table % -> % plot % -]

inspected cell layout:
<choose cell model>
```

the **New Template** intention found on the reduction rule node. See detailed instructions in [campagne2014mps]. When configuring the type of the output node (under **content node:**), use Lines, from the language *org.campagnelab.textoutput* to produce text with the MPS Generator aspect.

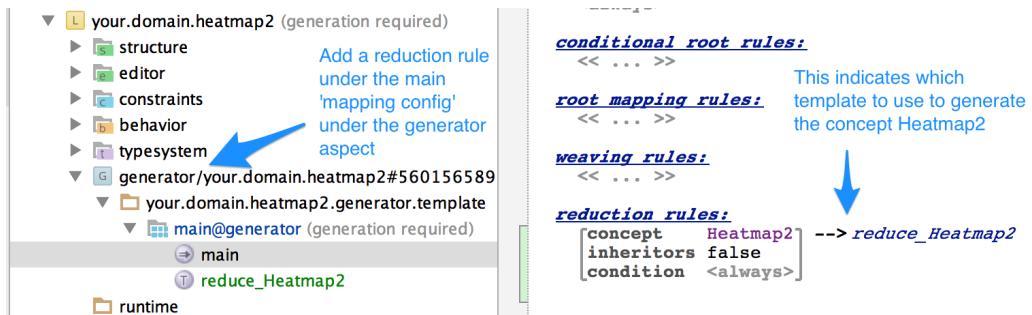

Figure 8.4: Generate R Code: Step 1. Start by adding a reduction rule.

The simplest template we can build for the `Heatmap2` concept is shown on Figure 8.5. Simply calling the `heatmap.2` function is a good start, but trying to run this will fail because the function is not part of a plain R distribution. The next section explains how to install the `gplots` R package which provides the function and activate it.

8.5.1 Adding package and library support

MetaR makes it easy to install R packages as they are needed by an analysis. For this to work, we need to declare that the `Heatmap2` concept depends on the `gplots` R package. We can do this by overriding the default Statement behavior method called `dependencies()`. This method is expected to return the list of package names that must be installed and loaded before the statement can execute. To override the method, navigate to the `Heatmap2` concept in the editor, select the behavior tab, create the behavior and when the empty behavior is shown, select Override Behavior Method (see Figure 8.6). Replace the body of the method with

```
return new singleton<string>("gplots");
```

Figure 8.7 shows the complete method. Rebuild the language, then the solution. When you run the Analysis, you will see that the `gplots` package is being installed:

```

...
Loading required package: gplots
Installing package into '/Users/fac2003/.metaRlibs'
(as 'lib' is unspecified)
also installing the dependencies 'bitops', 'gtools', 'gdata',
'caTools'

trying URL ....

```

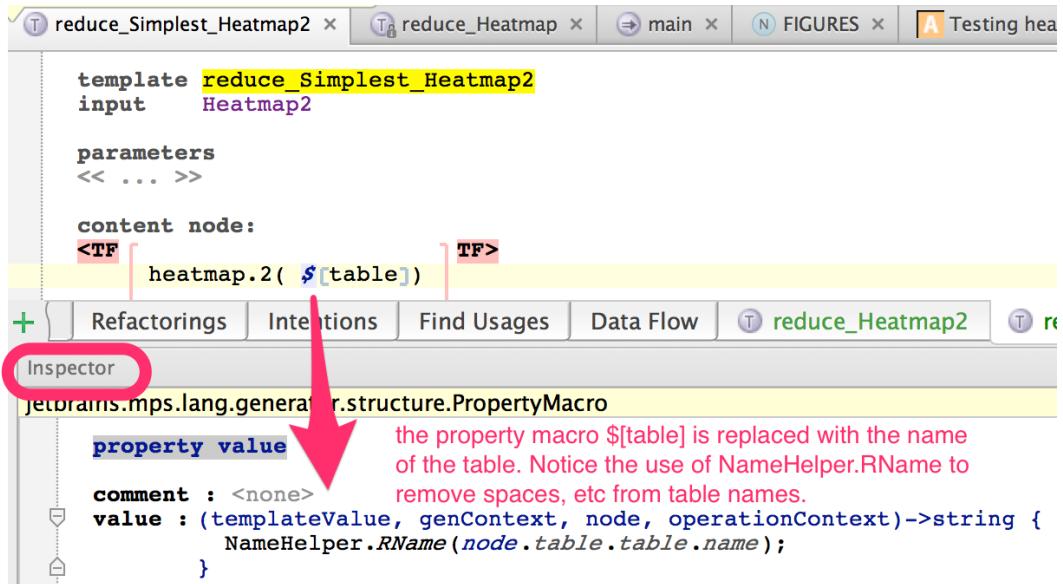

Figure 8.5: **Simplest template.** The template simply converts any node of the Heatmap2 concept to a line of R code that calls the heatmap.2 function with the table as an argument. Notice the use of a property macro to obtain the R name of the table variable from the node table attribute. Open the to see what value the macro will take when a node is generated to R code.

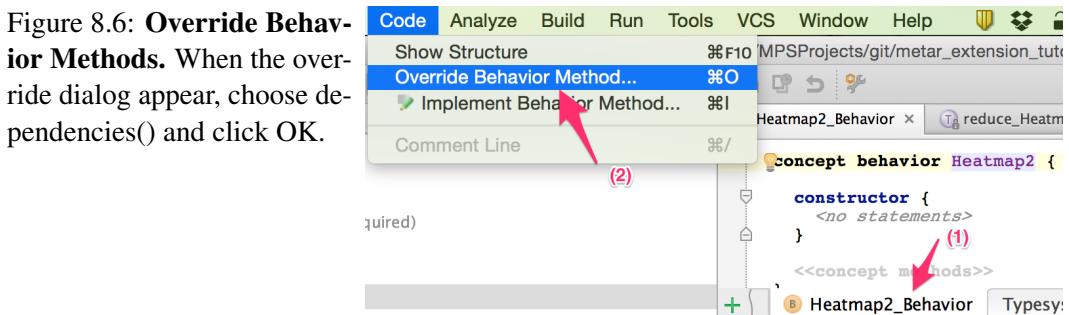

Figure 8.6: **Override Behavior Methods.** When the override dialog appear, choose dependencies() and click OK.

8.5.2 Adjust Generator Priorities

Adjust the generator priorities as shown in Figure 8.8. To set priorities, you need to define a Design dependency on `org.campagnelab.metar.tables` in the generator aspect Module Properties dialog.

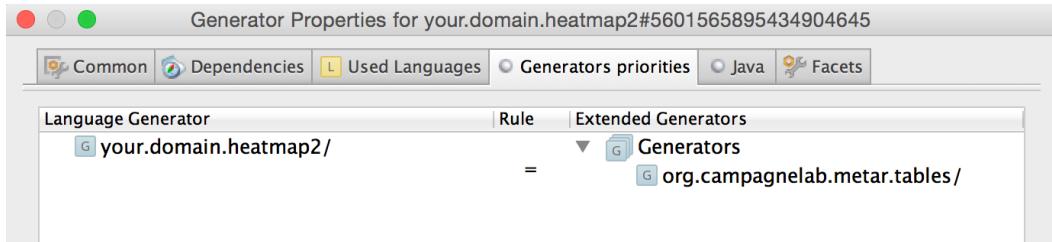

Figure 8.8: Adjust Generator Priorities. Generation of the Heatmap2 concept has to happen in the same generation phase as the generation of the `org.campagnelab.metar.tables` concepts. Failure to adjust priorities may result in table names not being correctly inserted in the `heatmap.2` function call.

8.5.3 Redirecting the plot output

The next problem with the simple template is that it fails to write the image of the plot in location where MetaR can find it. This is needed to display the plot preview, or to make it possible to use plots with the `multiplot` statement. The strategy we use to handle both cases is to wrap the actual plotting code inside a `plot_xxx` function. The function is named with the id of the statement that generates the plot, so that we can easily refer to it in other places where the plot should be reused. We start by defining this function:

```
plot_ $[id]=function(t){
  heatmap.2(as.matrix(t))
}
```

The function accepts one argument: the name of the table to plot.

R The number of arguments is up to you, since you will generate both the function and the function calls.

The next step is to add the R code for generating a PNG file with the plot to show a preview in the inspector. To this end, we redirect the plot output with `png()`, call the `plot` function, and close the graphics output (`dev.off()`):

```
png(file= " $[plot.png]", width= $[w], height= $[h])
plot_ $id( $[table])
ignore <- dev.off()
```

Notice how the parameters of the `png` function are taken from the Plot node. For instance, the `$[plot.png]` macro will expand to

```
new RPath(node.plot.getPath()).toString();
```

8.5.4 Handling errors

Accurate error reporting is important to the end-user. When things do not go well and the R code fails, it is useful to know precisely which MetaR statement generated the error. In MetaR, this is done by taking advantage of the `tryCatch` R functions (see <http://mazamascience.com/WorkingWithData/?p=912>).

Because `tryCatch` is not particularly intuitive and is rather verbose, MetaR extends the `org.campagnelab.TextOutput` language with the `tryForNode` statement (concept name: TryAndReport). The `tryForNode` statement attempts to execute some lines of R code, and reports any errors that occur in these lines with a link to the statement that produced the error or warning. The `tryForNode` statement is also responsible for showing the `STATEMENT_EXECUTED/8289224569309332962/` lines in the Run tool, which are hyper-linked to statements in the editor.

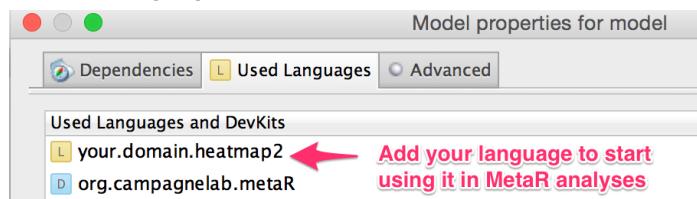

The statement `tryForNode` takes an ID, which is the result of the `id()` method defined for each MetaR statement. The value of the ID can be set as usual with a property macro (its value should be `node.id()`). Figure 8.9 shows the completed template for `Heatmap2`. While the statement only needs to call the `heatmap.2` function, handling possible errors and producing plots that can be reused to build multi-panel figures have added quite a few lines to the output.

MetaR 1.3.1.1 makes it easier to wrap `TextOutput` Lines into a `tryForNode` block. Select a node of type `Lines` (highlighted in blue braces) and invoke the intention `Wrap Lines in a TryForNode Block`. Note that this intention is not available for lines already inside a `tryForNode` block.

8.6 Using the New Language

Using the `your.domain.heatmap2` language in MetaR analyses requires adding the language under Used Languages, as shown here:

Once the language is added, you can create statements by typing the `Heatmap2` concept name. Figure 8.10 shows the result of using the new concept.

```

template reduce_Heatmap2
input Heatmap2

parameters
<< ... >>

content node:
<TF>
  plot_ $[id]=function(t){
    tryForNode $[id] {
      heatmap.2(as.matrix(t))
    }
    tryForNode $[nodeId] {
      png(file=" $[plot.png]", width= $[w], height= $[h])
      plot_ $[id]( $[table])
      ignore <- dev.off()
    }
  }
</TF>

```

Figure 8.9: Complete Generator for Heatmap2. This template wraps the `heatmap.2` function call inside a `plot` function (needed when building figures with multiple panels) and inside a `tryForNode` statement. The `tryForNode` statement generates to the `tryCatch` R language construct and appropriately reports errors to the end-user.

Figure 8.10: Heatmap2 Execution. This figure presents an Analysis using the new Heatmap2 concept and shows the resulting plot preview in the inspector (bottom right). Error handling and progress indicators can be seen on the bottom left.

8.7 Git Repository

This concludes this tutorial. You can find a project with the *heatmap2* language extension described in this Chapter at:

`https://bitbucket.org/campagnelaboratory/
metar_extension_tutorial`

$\text{ctrl} + \text{Esc} + \text{Up} + \text{F7}$	$\text{⌘} + \text{Esc} + \text{Up} + \text{F7}$	Highlight cell dependencies
$\text{ctrl} + \text{Up} + \text{F6}$	$\text{⌘} + \text{Up} + \text{F6}$	Highlight instances
$\text{ctrl} + \text{Up} + \text{F7}$	$\text{⌘} + \text{Up} + \text{F7}$	Highlight usages
$\text{ctrl} + \text{F}$	$\text{⌘} + \text{F}$	Find text
F3	F3	Find next
$\text{Up} + \text{F3}$	$\text{Up} + \text{F3}$	Find previous

Table 9.2: Usage and Text Search

Windows or Linux	MacOS	Action
<code>ctrl + M</code>	<code>⌘ + M</code>	Import model
<code>ctrl + L</code>	<code>⌘ + L</code>	Import language
<code>ctrl + R</code>	<code>⌘ + R</code>	Import model by root name

Table 9.3: Import

Windows or Linux	MacOS	Action
<code>ctrl + [Space]</code>	<code>ctrl + [Space]</code>	Code completion
<code>ctrl + ⌘ + click</code>	<code>⌘ + ⌘ + click</code>	Show descriptions of error or warning at caret
<code>⌘ + ⌘</code>	<code>⌘ + ⌘</code>	Show intention actions
<code>ctrl + ⌘ + T</code>	<code>⌘ + ⌘ + T</code>	Surround with...
<code>ctrl + X</code> or <code>ctrl + ⌘ + ⌘ + ⌘</code>	<code>⌘ + X</code>	Cut current line or selected block to buffer
<code>ctrl + C</code> <code>ctrl + Insert</code>	<code>⌘ + C</code>	Copy current line or selected block to buffer
<code>ctrl + V</code> <code>ctrl + ⌘ + ⌘</code>	<code>⌘ + V</code>	Paste from buffer
<code>ctrl + D</code>	<code>⌘ + D</code>	Up current line or selected block
<code>⌘ + F5</code>	<code>⌘ + F5</code>	Clone root
<code>ctrl + ⌘ + ⌘</code> or <code>ctrl + ⌘ + ⌘ + ⌘</code>	<code>⌘ + ⌘ + ⌘</code> or <code>⌘ + ⌘ + ⌘ + ⌘</code>	Expand or Shrink block selection region
<code>ctrl + ⌘ + ⌘ + ⌘</code> or <code>ctrl + ⌘ + ⌘ + ⌘ + ⌘</code>	<code>⌘ + ⌘ + ⌘ + ⌘</code> or <code>⌘ + ⌘ + ⌘ + ⌘ + ⌘</code>	Move statements Up or Down
<code>⌘ + Arrows</code>	<code>⌘ + Arrows</code>	Extend the selected region to siblings
<code>ctrl + W</code>	<code>⌘ + W</code>	Select successively increasing code blocks
<code>ctrl + ⌘ + ⌘ + W</code>	<code>⌘ + ⌘ + ⌘ + W</code>	Decrease current selection to previous state

Table 9.4: Editing (Part 1/2)

Windows or Linux	MacOS	Action
<code>ctrl + Y</code>	<code>⌘ + Y</code>	Delete line
<code>ctrl + Z</code>	<code>⌘ + Z</code>	Undo
<code>ctrl + ⌘ + Z</code>	<code>⌘ + ⌘ + Z</code>	Redo
<code>≣ + F12</code>	<code>≣ + F12</code>	Show note in AST explorer
<code>F5</code>	<code>F5</code>	Refresh
<code>ctrl + MINUS</code>	<code>⌘ + MINUS</code>	Collapse
<code>ctrl + ⌘ + ⌘ + MINUS</code>	<code>⌘ + ⌘ + ⌘ + MINUS</code>	Collapse all
<code>ctrl + PLUS</code>	<code>⌘ + PLUS</code>	Expand
<code>ctrl + ⌘ + ⌘ + PLUS</code>	<code>⌘ + ⌘ + ⌘ + PLUS</code>	Expand all
<code>ctrl + ⌘ + ⌘ + 0-9</code>	<code>⌘ + ⌘ + ⌘ + 0-9</code>	Set bookmark
<code>ctrl + 0-9</code>	<code>ctrl + 0-9</code>	Go to bookmark
<code>Tab</code>	<code>Tab</code>	Move to the next cell
<code>⌘ + Tab</code>	<code>⌘ + Tab</code>	Move to the previous cell
<code>Insert</code>	<code>ctrl + N</code>	Create Root Node (in the Project View)

Table 9.5: Editing (Part 2/2)

Windows or Linux	MacOS	Action
<code>ctrl</code> + <code>B</code> or <code>ctrl</code> + <code>click</code>	<code>⌘</code> + <code>B</code> or <code>⌘</code> + <code>click</code>	Go to root node
<code>ctrl</code> + <code>N</code>	<code>⌘</code> + <code>N</code>	Go to declaration
<code>ctrl</code> + <code>↑</code> + <code>N</code>	<code>⌘</code> + <code>↑</code> + <code>N</code>	Go to file
<code>ctrl</code> + <code>G</code>	<code>⌘</code> + <code>G</code>	Go to node by id
<code>ctrl</code> + <code>↑</code> + <code>A</code>	<code>⌘</code> + <code>↑</code> + <code>A</code>	Go to action by name
<code>ctrl</code> + <code>←</code> + <code>↑</code> + <code>M</code>	<code>⌘</code> + <code>←</code> + <code>↑</code> + <code>M</code>	Go to model
<code>ctrl</code> + <code>←</code> + <code>↑</code> + <code>S</code>	<code>⌘</code> + <code>←</code> + <code>↑</code> + <code>S</code>	Go to solution
<code>ctrl</code> + <code>↑</code> + <code>S</code>	<code>⌘</code> + <code>↑</code> + <code>S</code>	Go to concept declaration
<code>ctrl</code> + <code>↑</code> + <code>E</code>	<code>⌘</code> + <code>↑</code> + <code>E</code>	Go to concept editor declaration
<code>←</code> + <code>Left</code> or <code>Right</code>	<code>ctrl</code> + <code>Left</code> or <code>Right</code>	Go to next or previous editor tab
<code>Esc</code>	<code>Esc</code>	Go to editor (from tool window)
<code>↑</code> + <code>Esc</code>	<code>↑</code> + <code>Esc</code>	Hide active or last active window
<code>↑</code> + <code>F12</code>	<code>↑</code> + <code>F12</code>	Restore default window layout
<code>ctrl</code> + <code>↑</code> + <code>F12</code> <code>F12</code>	<code>⌘</code> + <code>↑</code> + <code>F12</code> <code>F12</code>	Hide all tool windows Jump to the last tool window

Table 9.6: Navigation (Part 1/2)

Windows or Linux	MacOS	Action
<code>ctrl + E</code> <code>ctrl + ⌘ + Left</code> or <code>Right</code> <code>⌘ + F1</code>	<code>⌘ + E</code> <code>⌘ + ⌘ + Left</code> or <code>Right</code> <code>⌘ + F1</code>	Recent nodes popup Navigate back or forward Select current node in any view
<code>ctrl + H</code> <code>F4</code> or <code>⌞</code> <code>ctrl + F4</code> <code>⌞ + 2</code> <code>ctrl + F10</code> <code>ctrl + ⌘ +)</code> <code>ctrl + ⌘ + (</code> <code>ctrl + ⌈ + Right</code> <code>ctrl + ⌈ + Left</code> <code>ctrl + ⌘ + ⌈ + R</code> <code>ctrl + ⌈ + T</code> <code>ctrl + H</code> <code>ctrl + I</code>	<code>⌘ + H</code> <code>F4</code> or <code>⌞</code> <code>⌘ + F4</code> <code>⌞ + 2</code> <code>⌘ + F10</code> <code>⌘ + ⌘ +)</code> <code>⌘ + ⌘ + (</code> <code>ctrl + ⌈ + Right</code> <code>ctrl + ⌈ + Left</code> <code>⌘ + ⌘ + ⌈ + R</code> <code>⌘ + ⌈ + T</code> <code>ctrl + H</code> <code>⌘ + I</code>	Concept or Class hierarchy Edit source or View source Close active editor tab Go to inspector Show structure Go to next project window Go to previous project window Go to next aspect tab Go to previous aspect tab Go to type-system rules Show type Show in hierarchy view Inspect node

Table 9.7: Navigation (Part 2/2)

Windows or Linux	MacOS	Action
<code>ctrl + F9</code>	<code>⌘ + F9</code>	Generate current module
<code>ctrl + ⌈ + F9</code>	<code>⌘ + ⌈ + F9</code>	Generate current model
<code>⌈ + F10</code>	<code>⌈ + F10</code>	Run
<code>ctrl + ⌈ + F10</code>	<code>⌘ + ⌈ + F10</code>	Run context configuration
<code>⌞ + ⌈ + F10</code>	<code>⌞ + ⌈ + F10</code>	Select and run a configuration
<code>ctrl + ⌈ + F9</code>	<code>⌘ + ⌈ + F9</code>	Debug context configuration
<code>⌞ + ⌈ + F9</code>	<code>⌞ + ⌈ + F9</code>	Select and debug a configuration
<code>ctrl + ⌘ + ⌈ + ⌈ + F9</code>	<code>⌘ + ⌘ + ⌈ + ⌈ + F9</code>	Preview generated text
<code>ctrl + ⌈ + X</code>	<code>⌘ + ⌈ + X</code>	Show type-system trace

Table 9.8: Generation

Windows or Linux	MacOS	Action
<code>ctrl + O</code>	<code>⌘ + O</code>	Override methods
<code>ctrl + I</code>	<code>⌘ + I</code>	Implement methods
<code>ctrl + /</code>	<code>⌘ + /</code>	Comment or uncomment with block comment
<code>ctrl + F12</code>	<code>⌘ + F12</code>	Show nodes
<code>ctrl + P</code>	<code>⌘ + P</code>	Show parameters
<code>ctrl + Q</code>	<code>ctrl + Q</code>	Show node information
<code>ctrl + Insert</code>	<code>ctrl + N</code>	Create new ...
<code>ctrl + ⌂ + B</code>	<code>⌘ + ⌂ + B</code>	Go to overriding methods or Go to inherited classifiers
<code>ctrl + U</code>	<code>⌘ + U</code>	Go to overridden method

Table 9.9: BaseLanguage and Editing

Windows or Linux	MacOS	Action
<code>ctrl + K</code>	<code>⌘ + K</code>	Commit project to VCS
<code>ctrl + T</code>	<code>⌘ + T</code>	Update project from VCS
<code>ctrl + V</code>	<code>ctrl + V</code>	VCS operations popup
<code>ctrl + ⌂ + A</code>	<code>⌘ + ⌂ + A</code>	Add to VCS
<code>ctrl + ⌂ + E</code>	<code>⌘ + ⌂ + E</code>	Browse history
<code>ctrl + D</code>	<code>⌘ + D</code>	Show differences

Table 9.10: Version Control System and Local History

Windows or Linux	MacOS	Action
<code>F6</code>	<code>F6</code>	Move
<code>↑ + F6</code>	<code>↑ + F6</code>	Rename
<code>⌫ + ⌂</code>	<code>⌫ + ⌂</code>	Safe Delete
<code>ctrl + ⌂ + N</code>	<code>⌘ + ⌂ + N</code>	Inline
<code>ctrl + ⌂ + M</code>	<code>⌘ + ⌂ + M</code>	Extract Method
<code>ctrl + ⌂ + V</code>	<code>⌘ + ⌂ + V</code>	Introduce Variable
<code>ctrl + ⌂ + C</code>	<code>⌘ + ⌂ + C</code>	Introduce constant
<code>ctrl + ⌂ + F</code>	<code>⌘ + ⌂ + F</code>	Introduce field
<code>ctrl + ⌂ + P</code>	<code>⌘ + ⌂ + P</code>	Extract parameter
<code>ctrl + ⌂ + M</code>	<code>⌘ + ⌂ + M</code>	Extract method
<code>ctrl + ⌂ + N</code>	<code>⌘ + ⌂ + N</code>	Inline

Table 9.11: Refactoring

Windows or Linux	MacOS	Action
F8	F8	Step over
F7	F7	Step into
↑ + F8	↑ + F8	Step out
F9	F9	Resume
⌘ + F8	⌘ + F8	Evaluate expression
ctrl + F8	⌘ + F8	Toggle breakpoints
ctrl + ↑ + F8	⌘ + ↑ + F8	View breakpoints

Table 9.12: Debugger

List of Figures

1.1	The Quick Start menu.	13
1.2	The New Project Dialog.	13
2.1	New Table.	16
2.2	Example Table.	17
2.3	Empty Column Group Container.	17
2.4	New Group.	17
2.5	Example Group Container.	18
2.6	Content of a Sample Annotation Table	19
2.7	Table with Samples and Groups	20
2.8	Intention to Annotate a Table using another Table	20
2.9	Covariate Table	21
2.10	Intention to add a Covariate Table	22
2.11	Column Group Annotation	22
2.12	How to activate the Table Viewer Tool	23
2.13	The Table Viewer Tool in the MPS UI	24
2.14	Visualization Options for Table Viewer Tool	24
2.15	The Table Viewer Tool	25
3.1	New MetaR Analysis Root Node.	27
3.2	Auto-completion Dialog for Statements.	28

3.3	Typing Statement Aliases.	28
3.4	New Style.	29
3.5	Adding Style Items to a Style.	29
3.6	Create New Style on Statements.	30
3.7	Style with restricted Items.	30
3.8	Styles visible from a Statement.	30
3.9	New Write Statement	31
3.10	New Sets of Ids.	32
3.11	Example of a user defined Sets of Ids.	32
3.12	New Subset Rows Statement.	32
3.13	Subset Rows Examples.	32
3.14	Subset Rows Examples.	33
3.15	New Join Statement.	34
3.16	Sample input tables for Join Statement.	35
3.17	Results Table for Join using by Column Strategy.	35
3.18	Results Table for Join using by Group Strategy.	36
3.19	Example of Join Statement.	36
3.20	Column Preview for Result Table.	37
3.21	New Boxplot Statement.	37
3.22	Color Palette Item.	38
3.23	Color Item.	39
3.24	New Fit X by Y.	39
3.25	New Heatmap.	40
3.26	Example of Heatmap Plot.	41
3.27	Heatmap With Annotations.	42
3.28	New Venn Diagram.	42
3.29	Sets type of venn diagram.	42
3.30	Example of Venn Diagram with Three Sets.	43
3.31	New Multiplot Statement.	44
3.32	Example of Multiplot.	45
3.33	New Render Statement.	45

4.1	Download the MetaR Docker Image.	47
4.2	Docker Configuration Dialog.	48
4.3	Run With Docker.	49
5.1	Error When Typing the EdgeR Alias.	51
5.2	New EdgeR Statement.	51
5.3	EdgeR Example.	53
6.1	New Limma Voom Statement.	55
6.2	Limma Voom Example.	56
7.1	New Query Biomart Statement.	57
7.2	Select an attribute in a biomart dataset.	58
7.3	New Biomart Filter	59
8.1	Heatmap2 Concept.	62
8.2	Complete Heatmap2 Concept.	63
8.3	Editor of the Heatmap2 Statement.	63
8.4	Generate R Code: Step 1.	64
8.5	Simplest template.	65
8.6	Override Behavior Methods.	65
8.7	Complete Dependencies Behavior Method.	65
8.8	Adjust Generator Priorities.	66
8.9	Complete Generator for Heatmap2.	68
8.10	Heatmap2 Execution.	68
